The Wilder Peach.—We may safely assert, says the "Gardener's Monthly," that the bewis of new fruits have been widely advertised on much inferior merit to this. We should not be at all surprised if this Wilder Peach should distance all the early ones yet brought out. Of course a careful test would be necessary to give this as a positive opinion, but we really think the facts point that way.

Fruit Tree Management.—Mr. Munn, Secretary of the Missouri State Horticultural Society, does not believe in describing the management of fruit trees in the usual high colours in which it is painted. In his last report he says:—The extreme simplicity of fruit culture has been much insisted on. In this many have been greatly misled. There is a necessity for practical education. More knowledge, more experience, more of the technical training must be had to give a chance of success.

The American Cranberry in Europe.—M. Bonchi, reporting on experiments in Germany with American Cranberry (*Vaccinium macrocarpum*) strongly recommends it for general cultivation, as it will flourish in a variety of soils. He calculates the crop to be one that would afford good remuneration to the cultivator. It would, of course, thrive admirably on many of our boggy soils. The berries, as preserved by the American growers, form one of the most agreeable preserves with which we are acquainted.

How Fruit is Preserved in Russia.—Lime is slaked in water in which a little crocus is then dissolved. It is then allowed to fall to powder, and is spread over the bottom of a deal box to about one inch in thickness. A sheet of paper is laid next, and upon that the fruit; over the fruit is another sheet of paper, and then more lime, and so on till the box is full, then finely powdered charcoal is packed in the corners and the lid tightly closed. Fruit thus enclosed is said to remain sound for a long time, but further particulars as to the kinds of fruit preserved, &c., are not given.

THE INDOOR GARDEN.

THE COCA PLANT.

(ERYTHROXYLON COCA.)

CONSIDERABLE attention has recently been directed to the stimulating and other properties possessed by this plant, living specimens of which may now be seen at Kew, in the Royal Botanic Gardens, Regent's Park, and also in some of the best London nurseries, where it forms a low shrub from 3 ft. to 4 ft. in height. So far as we can discover, it is a very variable plant, some of the specimens being much branched and the leaves very different from each other both in size and shape. Our illustration represents a branchlet and was taken from a plant which recently flowered in the Economic House at Kew; it is precisely the same in habit as specimens of the wild plant in the Kew Herbarium. Coca leaves have long been, and still are, extensively used as a masticatory by the inhabitants of the Pacific side of South America. In Peru, more especially, the custom of chewing the leaves of this plant is said to be of great antiquity; indeed, it is said to have originated with the Incas, and at the present time is common through New Grenada, Quito, and Peru, and also on the banks of the Rio Negro. The Indians always carry with them a little bag of the dried leaves and a gourd containing finely powdered lime, which is mixed with the leaf before chewing. Used in moderation, Coca is said to pleasingly excite the imagination, and it also powerfully stimulates the nervous system. In illustration of this, Dr. Spruce remarks that an Indian with a supply of his favourite Coca leaf or Spadic, will travel two or three days without food and without showing any desire for sleep. Among recent contributions to the history and effects of this plant we may allude to a paper read before the April meeting of the Edinburgh Botanical Society, from which it appears that without doubt the leaves of the Coca, when rightly prepared and used discreetly, possess the effects ascribed to them by all travellers in Peru since Pöppig was there in 1827, but that their effects are not always precisely the same on different individuals. From experiments conducted by Sir R. Christison, the author of the paper above cited, and those of fourteen other gentlemen who undertook to try the plant at his request, the following conclusions have been arrived at:—(1) That taken in quantities of two drachms by healthy persons it has no injurious, unpleasant, or suspicious effect whatever; (2) that in a very few cases this dose of an inferior sample had no effect at all; (3) that in by much the greater number of instances, and with a fine sample in every case, extreme fatigue was removed and prevented from returning, and that no doubt can exist that in such persons its restorative and preventive powers will render protracted exercise easy, without any subsequent harm, so far as the restorative is concerned; (4) that it does not in the end impair the appetite or digestion, although hunger, even after long fasting, is taken away for an hour or two; (5) that the use of it probably does not agree with more than a very moderate use of alcoholic stimulants; at the same time the paper

avoided all reference to the possible medicinal uses of this plant. Similar conclusions have also been arrived at by Professor Bouchardat, of Paris, who considers that its services in therapeutics have been most valuable—almost equal to those of Cinchona, and that as a nervous and muscular stimulant it ranks with tea and coffee. On the other hand, evidence is not wanting to show that its effects (like those of Tobacco, Opium, Hemp-resin, Gunjah or Bhang, alcohol, and other vegetable stimulants) are certainly highly injurious when used habitually or in excess. A confirmed conqueror, as an habitual chewer is termed, is said to be invariably known by his haggard look, gloomy and solitary habit, listless inability and disinclination for any active employment. Its use is regarded by Europeans as befitting only the Indians; nevertheless, many whites are addicted to it. Dr. Weddell, who inquired very carefully into its effects on the constitution, states as the result of his observation the opinion that its habitual use acts on Europeans more prejudicially than on the

Indians accustomed to it from early years; and in some cases attributed to its abuse a peculiar aberration of intellect, characterised by hallucinations. Dr. Mantegazza fully confirms the statements of Pöppig, and carefully describes its effects, stating the result of intemperance in its use to be frequently confirmed idiocy. The principle to which the effects of the Coca leaf is due has been named Cocaine, but much remains yet to be done before we can speak with any precision as to the properties and uses of this comparatively modern introduction to the Pharmacopœia. The plant is easily cultivated in an ordinary plant stove in a compost of fresh fibrous loam, leaf-mould, and sand; when growing it requires copious supplies of water at the root, and frequent syringings with tepid water keep down insect-pests. Cuttings of both stem and root may be employed for purposes of propagation. There are about seventy other species of Erythroxylon, some of which have stimulating qualities, while others furnish a tonic bark somewhat resembling that of Cinchona. The bark of one species—*E. tuberosum*—supplies a reddish dye. The majority of the species are natives of South America and the West Indies, but others are found in Madagascar and the Mauritius. In nearly all the species a distinct pale band runs up the centre of the back of the leaf, as shown in our engraving; indeed, in some descriptions of the leaf of the Coca plant, we find it stated that two veins, in addition to the midrib, run parallel to the margin, as in *Melastomus*. B.

The Coca Plant.—Leaf natural size, single flower, and ovary enlarged.

THE GLEICHENIAS.

THESE constitute one of the most beautiful groups belonging to the whole family of Ferns; the different species of which the genus consists are divided into two tolerably distinct sections, namely, the *Gleichenias* properly so called, in which the minor segments of the fronds or pinnules are orbicular or roundish; and the *Mertensia* group, the growth of which is more erect and the pinnules linear. As regards culture these two sections differ but little, if we except tempera-

ture; the true *Gleichenias*, being natives of Australia, New Caledonia, New Zealand, and Tasmania, will luxuriate in a cool plant stove; while the *Mertensia* group, which consists of natives of Ceylon, Penang, Malacca, Hong Kong, Assam, Jamaica, and Trinidad, require a warm stove. Of *Gleichenias*, some twenty or thirty are named in Hooker and Baker's "Synopsis Filicum," but for decorative or exhibition purposes the kinds alluded to below are the best. None of them should be sown in deep pots, as the fronds rise from slender rhizomes that creep near the surface. The compost in which they succeed best is one capable of retaining its porosity for a long time, as, when once established, they do not like being disturbed. Fibrous peat, broken up into pieces the size of an egg, forms a good basis, and to this may be added about one-fifth of coarse sand-stone grit or well-washed road or river sand. The ordinary white sand, so generally recommended and used for Ferns and other plants, is too fine for the purpose, and allows the soil to clog in a comparatively short time after the plants are re-potted. To the above a little good fibrous peat may be added in the case of robust growing kinds, and especial care must be taken to drain the pots or pans employed in such a way that water cannot stagnate in the compost. Like all Ferns, *Gleichenias* require a copious supply of moisture, both at the root and in the atmosphere, especially when growing, but the soil, as I have said, must never be permitted to become water-logged. Insect-pests must, as a matter of course, be carefully guarded against. Green fly is apt to appear on the young fronds in the spring, and brown and white scale often do great damage unless kept from spreading, as it is almost an impossibility to eradicate them from large specimens when once they obtain a footing.

I.—*Gleichenias*, properly so called.

Pinnules round, arranged closely in double or bead-like rows, and often pouched or concave below.

Gleichenia alpina.—This is a compact Tasmanian species, the fronds of which rarely exceed 12 in. in height; the divisions of the frond are about an inch in length, the minor divisions being round and not pouched below, and of a fresh bright green colour above. When well grown it forms an attractive little specimen, which succeeds perfectly in a cool Fernery or pit.

G. circinata.—This is generally grown in gardens under the name of *G. microphylla*; it produces elegantly-curved fronds of a dense green colour, the minor segments being roundish in outline and not concave below. Although, in general appearance, it somewhat resembles the last, it is much more robust and larger in all its parts. This is a native of New South Wales and Tasmania, and is one of the best known of all *Gleichenias*. A very distinct variety of this plant is not infrequently met with in good gardens under the name of *G. circinata glauca*, which, in addition to being much more luxuriant in growth than the type, has thicker fronds, and the young growths and the under surface of the pinnules have a distinct glaucous hue. It is generally imported from New Zealand, and is well worth culture as one of the most robust and beautiful of the group to which it belongs.

G. dicarpa.—Of this the annexed illustration (p. 447) gives an excellent idea; it is one of the most elegant of all *Gleichenias*, and a kind that may be grown successfully in a warm greenhouse. As in many other species, its long fronds branch dichotomously, and their minor segments are of a bright dense green colour, the under surfaces being pouched or concave. The slender stipes are densely hairy, but the other parts of the fronds are smooth. Good specimens of it measure from 2 ft. to 4 ft. in height, and about a yard in diameter. It is a Tasmanian species, and being a good grower and one of the best of the section to which it belongs, it well deserves culture.

G. hecistophylla.—This attractive New Zealand species resembles the last in general habit of growth, but the divisions of the fronds are larger. The stipes and rachis are densely covered with short brown hairs, the remaining portion of the fronds being smooth and of a dense but bright green tint. When grown in a shallow pan of fresh open compost, in a temperate and humid atmosphere, this makes a handsome specimen, either for ordinary decorative purposes or for exhibition.

G. rupestris.—Of this, perhaps the rarest of all cultivated species, the best specimen I ever saw was one grown by Mr. Petch at Manley Hall, near Manchester; it was about 4 ft. in height, and nearly

a yard in diameter. Like the others, it is evergreen, and the stems are of a dull reddish-purple colour, the minor divisions of the fronds being bright green above and glaucous beneath, but not concave or pouched. It is a native of New South Wales, and when better known will doubtless become a general favourite with all growers of choice Ferns.

G. semivestita.—This comes from New Caledonia, and requires a stove temperature, if success in its culture be the object aimed at. Although generally considered by cultivators to be a species, it is, without doubt, only a distinct form of *G. circinata*. Its stems and branches are covered with short red or brownish hairs, and the minor divisions or pinnae are of a dense green colour. When well grown it makes a very handsome specimen, fully 4 ft. in height, and nearly as much in diameter. Its fronds, in a cut state, are very useful for many purposes, and if well-developed pieces be selected and immersed in water for half-an-hour or so before they are associated with flowers or other Ferns, they will be found to remain fresh for a day or even longer.

G. Speluncæ.—Like the last this is only a distinct form of *G. circinata*, which must be regarded as perhaps the most ubiquitous and variable plant in the whole genus to which it belongs. The fronds are broader than those of the type, of a pale green colour above, and most distinctly glaucous, indeed, almost silvery, beneath; the pinnae are not pouched like those of *G. dicarpa* and others. Well-grown plants of this are very handsome and effective, especially when contrasted with more sombre-tinted kinds. It is a native of New South Wales and also of Tasmania. It is now common in gardens and for all decorative purposes; it is one of the best and most distinct in the whole section in which it is placed.

II.—False *Gleichenias* or *Mertensias*.

Pinnules linear, pectinate or comb-like in arrangement, and often serrate.

G. Cunninghamii.—This beautiful New Zealand species is at present rare in cultivation. It is upright in habit, and its fan-like fronds, which often reach from 3 ft. to 4 ft. in height, are peculiarly bright green above and distinctly glaucous beneath. The young growths are covered with large brown scales, which form quite a distinctive feature. It grows well under ordinary treatment in a warm greenhouse or conservatory, and when more plentiful cannot fail to be a favourite.

G. dichotoma.—This is a very widely distributed species, and one which is very variable in habit. It is found throughout the tropical and sub-tropical regions of the southern hemisphere, and is one of the most common species in cultivation. Its long branching fronds are borne on a slender rhizome, the ultimate segments of which are from 8 in. to 12 in. in length, and divided into regular comb-like or pinnate divisions. The fronds are of a soft and pleasing shade of green above and glaucous beneath. When well grown in a cool stove temperature it makes a handsome specimen, either for ordinary decorative purposes or for exhibition. It is a Fern which should be in every good collection.

G. flabellata.—This robust, erect-growing plant, from Australia and Tasmania, is of easy culture and noble proportions. Specimens of it, 5 ft. in height and 10 ft. or even more in diameter, are not uncommon, and few cool-growing evergreen Ferns equal it in freshness and beauty. It succeeds well in a shallow, well-drained pot or tub of fibrous loam, peat, and coarse sand, and requires a copious supply of moisture. It is one of the hardest species in the whole genus, fine specimens of it being known to withstand 2° or 3° of frost without sustaining any injury. It is, however, inadvisable to allow the temperature to fall so low if it can be avoided. The fronds have elegant fan-like divisions, of a deep green colour, and are invaluable for cutting, as they remain fresh in water for several days.

G. furcata.—This comparatively little known West Indian plant grows 2 ft. or 3 ft. in height, and has fronds which branch dichotomously, as is generally the case with other plants of this group. The pinnae are linear, and rather deeply serrated, of a soft green colour, and slightly downy. It is a plant which requires a warm stove temperature and a fresh, well-drained compost.

G. pectinata.—This appears to differ but little from *G. dichotoma*; it is, however, less robust and more elegant in habit, and the fronds are not so finely divided, and they are more distinctly glaucous beneath.

Many other species of *Gleichenia* are known through books and herbaria, but the kinds just named consist of the most beautiful of those which are grown in gardens, and they are amply sufficient for the most complete general collection of decorative Ferns. B.

CULTURE OF AMARYLLIDS.

THESE are bulbous plants, some of which are evergreen, others shed their leaves in winter, the principal difference in their culture being that the evergreen kinds, although requiring to be kept much drier at the roots during the winter season, than the others must not be allowed ever to become quite dry—a condition necessary with those that are deciduous. Of the first species introduced, a few are from the Cape of Good Hope and the West Indies, but the greater number are indigenous to Brazil and the adjacent countries. From these have sprung the present race of splendid hybrids, possessing a free habit of blooming, and producing large and truly gorgeous flowers, wherein the striping and blending of soft and intensely deep colours are combined in a way that is not surpassed by any plants in cultivation. They possess the double merits of being easily grown, and not getting too large for those who have not the convenience of large stoves, which are required for the successful cultivation of some varieties. They succeed well in good fibrous loam of a strong nature, with just as much sand added as will ensure its not getting sour and impervious to the plentiful supply of water they require during growth. There is one thing in their management that those who essay their culture will do well to bear in mind—that they do not like their roots disturbed; this especially applies to the evergreen kinds. This is the less necessary, as they do not need a great deal of pot-room, always succeeding best when the roots have well filled the soil; at the same time this must not be carried too far by allowing them to starve for want of sufficient root-space, or the flowers they produce will not be so numerous or so fine, neither will they increase by throwing off the usual quantity of offsets. Some who have written upon the cultivation of Amaryllids have advised their being grown in a mixture of peat and loam, but my experience has always been to the effect that anything in the shape of peat or light vegetable mould is fatal to their well-being. They can be raised easily from seed, and those who take an interest in hybridising have an ample field before them in which to obtain new varieties. When the seeds are ripe they should be sown in well-drained pans filled with good yellow loam, to which has been added as much sand as will keep the soil in a condition that the water can pass through it; cover the seeds slightly, and place the pans in an intermediate temperature of 60° in the night, and proportionately higher in the daytime; give as much water as will keep the soil moist. When the young plants make their appearance, allow them plenty of light; as the days lengthen, give 5° more heat in the night and 10° or 15° in the day; let them have enough water, and admit air, as they will not make satisfactory progress if too much confined. It is not well to disturb them from the seed-pans until they have

made several leaves and the bulbs have begun to form, which condition they will attain towards the close of summer, if all have gone well with them now, as the object is to keep them in growth during the summer and winter for a couple of years, in order to save time. They should be placed singly in small pots, well drained, and the soil pressed quite solid about the roots. They generally succeed better when the greater portion of the bulb is covered in the soil than when potted higher above it. This applies to all their stages of growth. At once replace them at the coolest end of the stove, and keep them through the autumn and winter at 55° in the night and

a little more in the day, attending to them regularly with water. As solar heat increases, raise the temperature proportionately, and as soon as the soil is well filled with roots, shift them into 4-in. or 5-in. pots, draining sufficiently and making the soil quite solid as in the first potting. Grow them on without delay by constant heat and moisture, giving them plenty of light all through the summer and autumn; winter them in a similar temperature; in spring move them into 6-in. pots, and treat them in every way as in the past summers; in the autumn place them where they will be under the ripening influence of all the sun and air possible, and gradually withhold water; through the winter place them on an airy shelf in a temperature of 55°, with just enough water to prevent the leaves from flagging; in spring give more heat and moisture. If the bulbs have attained the strength that they should have from the treatment prescribed, most of them will flower; after which give those that appear to require it 7-in. pots, and place them through the summer under similar conditions to promote growth as hitherto recommended, and in the autumn and winter repeat the ripening and resting processes, but never attempt to keep them too cool in winter; through this cause innumerable quantities of these fine plants have been lost. In their native country the only change they are subject to is from hot and damp in their growing season to equally hot and dry during the period of rest; consequently they will not bear to be kept too cold in the winter.

Gleichenia dicarpa.

For a time they will bear a lower temperature than that above given for their season of rest, but there is always danger of their decaying when so treated, and it also impairs their strength. In succeeding summers give small shifts when it is evident that they need more room, but not otherwise; as they get strong they will push offsets that can be taken off and grown on singly, managing them as recommended for plants raised from seed. The above treatment of course applies to seedlings that have been raised from evergreen kinds, and are similar in habit to the parents. To the deciduous kinds no water must be given from the time when the growth is fully matured and ripened up in the autumn, until they are to be started in spring; in other respects the treatment required is the same.

Both the evergreen and deciduous kinds want a plentiful supply of water whilst they are making growth; any stint at this stage will be sure to impair their strength and inflict serious injury. They will also be benefited at this time by a frequent supply of manure-water not too strong. Within the last few years this splendid genus of plants has received by many plant growers the attention it deserves, and has emerged from a state of comparative neglect to which it seems unaccountable it should ever have been consigned; yet such undoubtedly is the case, for there is ample evidence to prove that Amaryllids were much more generally grown half a century ago than they are at present.

Aphides often attack the young leaves and unexpanded flowers; they can be destroyed by fumigating with tobacco, or by sponging; the form of the leaves is such as to favour their being thus easily removed. Thrips and red spider will sometimes make their appearance if not syringed occasionally; for these lay the plants on their sides, and syringe freely with clean water. Scale and mealy bug will also live upon them; the best remedy for these is sponging, getting down to the base of the leaves, where the insects harbour.

THOMAS BAINES.

Daphne Cneorum Forc'd.—This may with advantage be added to the list of hardy plants suitable for forcing. Its adaptability for that purpose has been well exemplified this season in the Kingston Nurseries, where, according to the "Gardeners' Magazine," it has been forced in considerable numbers for indoor decoration. A remarkably fine example of this *Daphne* formed part of a group of old-fashioned flowers exhibited at the last meeting of the Royal Botanic Society, and was of itself sufficient to show that under a proper course of culture it makes a charming pot-plant. To ensure its flowering satisfactorily when forced it is simply necessary to pot up the plants in the autumn and plunge them in a bed of coal-ashes out-of-doors, where they can remain until the flower-buds are formed, and then to remove them to a temperature of about 65°. The flowers, it may be added, are delightfully fragrant, and when developed under glass are of a much more pleasing shade of pink than those produced in the open borders.

Saving Cineraria Seeds.—If a reputation for a superb strain be wanted, save seeds from named sorts only, of good habit and distinct colours. Avoid windmill-petaled kinds. To get up stock, plant the old and out-down plants out-of-doors behind a north wall in June, and water well during the summer. They will grow like weeds; in August take offsets from them; pot them in 4-in. pots, and as soon as they are well rooted, but before they get pot-bound, shift them again into 9-in. and 10-in. pots. Keep them cool during the winter, and do not pinch them unless they show flower just after potting. By May and June they will be in full flower, but not before, if they have been kept cool enough all the winter, and it is undesirable to have them in flower before that time, as there is then less chance of their seeding well. No artificial fertilization is necessary, but keep them near the light; give plenty of air, water liberally, and be careful to keep green fly in check by means of frequent and gentle fumigations before the plants come into flower. Steadily grown, vigorous plants are, however, little troubled with such pests. When the flowers fade, and show downy Thistle-like tops, pick them off and save them. Both before and after they come into flower, Cinerarias are much benefited by frequent waterings of weak liquid manure, which do much towards producing a good heavy sample of seed.—CHEF.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Wigandia latifolia.—This is a showy plant in conservatories at this time of the year. It produces fine heads of bloom of a beautiful many colour, the individual flowers having light centres, and measuring nearly 2 in. across; they are also sweet-scented. The plants, to bloom well, require to be at least one year old.—R. H. B.

Azalea mollis from Seed.—This lovely spring-blooming plant seeds freely and every batch of seedlings contains many varieties, the principal variation from the type being in colour, the prevailing tints being yellow, orange, and rose. Messrs. Ker & Co., of Liverpool, have raised some 400 or 500 seedlings of this *Azalea*, and of these some shown at the Manchester Exhibition the other day were much admired. Seedlings are raised with but little trouble, and apart from the charm of variety thus obtainable, the plants may be forced or retarded as desired, and they always flower freely.—B.

Heating by Lamps or Candles.—We have seen lamps used to keep frost out of small greenhouses, and candles have also been employed. The effects of both are increased by using metal reflectors above the flame. This prevents the heat from passing through the roof in a straight line, and almost doubles the heating power.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

NOTWITHSTANDING the prolonged cold winds, so many "daughters of the year" appeared during the past week that we can barely allude to them by name. The finest effects we have noticed during the week were afforded by the Hooped Petticoat *Narcissus*, especially the slender-leaved and dwarf form, by Veitch's *Primrose*, unfortunately named *P. cortusoides amona*, being wholly distinct, horticulturally from *P. cortusoides*. This, seen in established groups, in slightly sheltered positions in the open air, is the handsomest *Primrose* yet introduced; by *Phlox reptans*, masses of which are very brilliant seen at a distance; by the drooping buds of the Snow-drop *Anemone* (*A. sylvestris*); by the handsome golden buttons of the showy double *Buttercup* (*Ranunculus speciosus*); by some early *Irises* (hybrids between *I. obiensis* and *I. pumila*, raised in Ware's nursery); by the massive flowers of the double yellow *Tulip*; and by the variously-coloured forms of the Wood *Hyacinth* (*Scilla nutans*). The following plants were noted early in the week:—*Globularia nudicaulis*, *Viola canadensis*, *Orchis mascula*, *Anemone sylvestris*, *Othonna cheirifolia*, *Pæonia tenuifolia*, *Iberis coresefolia*, *Euphorbia Cyparissias*, *Aquilegia glandulosa*, *Alyssum atlanticum*, *Erysimum cochlearium*, *Valeriana montana*, *Ranunculus speciosus*, *Geranium tuberosum*, *Geranium phæum*, *Dodecatheon Jeffreyanum*, *Irish nudicaulis*, *I. germanica*, *I. obiensis*, *I. florentina*, *Tulipa Celsiana*, *Saxifraga granulata fl. pl.*, *Phlox procumbens*, *Iris tuberosa*, *Veronica repens*, *Viola pedata*, *Stylophorum diphyllum*, *Pyrethrum Tchihatchewi*, *Polemonium reptans*, *Primula Monroi*, *Vesicaria utriculata*, *Cheiranthus*, *Veronica prostrata*, *Primula viscosa*, *Narcissus tenuior*, *Scilla campanulata*, *Lychnis alpina*, *Coronilla minima*, *Lamium Orvala*, *Veronica chamaedrys*, *Narcissus biflorus*, *Narcissus dubius*, *Centranthus ruber*, *Saxifraga controversa*, *Saxifraga Geum*, *Saxifraga elegans*, *Ranunculus gramineus*, *Armeria vulgaris*, *Aquilegia vulgaris*, *Symphlytum officinale*, *Iris attica*, *Lunaria biennis*, *Collinsia verna*, *Lilium Thompsonianum*, *Fritillaria pyrenaica*, and *Narcissus triandrus*.

Mirror-globes in Gardens.—There is one offensive feature of Continental gardens, the Globe-mirror, concerning which we used to once cherish the hope that it would never be introduced to English gardens for our disquiet. We regretted, however, to see lately a very large one in the new Cannon Hill Park, at Birmingham. Such an object may perhaps amuse children; but we believe we express the sentiments of all lovers of English gardens who have been unfortunate enough to witness the object in question, when we say that a mirrored globe is sufficient to spoil the aspect of the poorest suburban tea-garden.

The Influence of Light upon the Colours of Flowers.—The influence of light upon the colours of flowers has been further investigated by M. Askenasy, who has described his results in the "Botanische Zeitung." It was found that (*Tulipa Gesneriana*) gave in darkness the same flowers as in light, and the flowers of the plants grown in darkness were in no wise altered when they were afterwards brought to the light, and the etiolated stems and leaves became green. On the other hand, *Hyacinthus orientalis* showed the influence of light in two ways; first, the light accelerated the development of the flowers, about fourteen days; then the flowers which grew in the dark were not indeed colourless, but the intensity of the colour was less, and its distribution was different from that in normal flowers. If the upper part of a cluster of flowers grown in darkness were cut off and exposed to light, there was, even after one day's action, a decided increase in the intensity of the colour, and in three days the flowers were nearly as deeply coloured as the normal flowers. *Scilla campanulata* developed in the dark normal flowers, in which the blue colour of the corolla was somewhat weaker than the uncovered specimens, while the reddish colour of the inflorescence of the normal plants was absent in the darkened ones. *Falmaria officinalis*, on the other hand, developed its flowers in darkness from the flower-buds quite normally; and also in the darkness the change of colour proper to this flower passed from red to blue, but the flowers that were developed later were more weakly coloured. The experiments here described show that many flowers need light to acquire their normal coloration, while others can dispense with it. Wherein lies the ground of this difference does not yet appear, and numerous farther experiments will be necessary before the phenomena can be reduced to order.

Double-flowered Meadow Saxifrage (*Saxifraga granulata* var. *flore-pleno*).

Bell-flowered Scilla (*Scilla campanulata*).

Twin-flowered Narcissus (*Narcissus biflorus*).

Common Thrift (*Statice Armeria*).

Large-flowered Thrift (*Statice pseudo-Armeria*).

Creeping Polemonium (*Polemonium reptans*).

Alpine Lychnis (*Lychnis alpina*).

Wood Hyacinth (*Scilla nutans*).

Red Dead Nettle (*Lamium Orvula*).

Honesty (*Lunaria biennis*).

Geranium tuberosum.

Wood Valerian (*Valeriana officinalis*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

TREES AND SHRUBS.

THE HOLLY IN BERRY.

MANY seem to have taken an unusual interest of late in berry-bearing Aucubas, and I have nothing to say against them as new additions to our berry-bearing shrubs; but they have always struck me as being inferior in appearance to a handsomely-shaped Holly tree laden with its bright scarlet fruit. The Holly is often used for planting under the shade of other trees, where it grows better than most other shrubs; it is then an evergreen and nothing more, for it does not bear fruit in the shade; but a Holly grown on the open lawn, tall, pyramidal, dense in foliage, and covered with bright fruit, is unmatched as an ornamental berry-bearing tree. For the last few years one of the most conspicuous objects in our grounds during the winter months has been a Holly tree. Hollies are usually raised from seed, and probably they vary in habit and fruitfulness, like the Horse Chestnut and similar trees; and probably the tree in question is a more than usually fruitful subject, for, though something must be allowed for a check which it received in lifting it on one occasion, it always was a freer bearer than most of its neighbours, and is generally so completely covered with fruit as to be a most conspicuous object a long way off. I think the case worth mentioning, as showing what might be accomplished by selecting seed for propagation from the most fruitful trees—presuming that they vary in this respect—and that in pleasure grounds it is well worth the trouble to give the Holly a little more attention than it usually receives. Seeding trees, I believe, make the best specimens, and if a good-shaped Holly be planted on the open lawn, it will almost invariably throw up one or two straight leaders, and assume a perfectly pyramidal form without any assistance from the knife at all, though a straggling shoot may be removed if needful. I have had opportunities of seeing the Holly grown in this way, and have seldom seen it otherwise than perfectly symmetrical in shape and dense in habit from bottom to top. Then as to berry-bearing, it is like other fruit trees: root-prune occasionally, and if the tree be at all fertile, it will bear profusely. Of course, it is not suggested that this trouble should be taken with all the Holly trees in the garden, but only with a few specimens here and there. Every two or three years cut a trench round them and shorten their roots; this is best done in May or August, and it is more necessary in deep and strong soils than in those of a light character; indeed, in retentive soils, which the Holly does not like, root-pruning is almost essential in order to secure a crop of berries. In ordinary cases, however, severe root-pruning, such as is sometimes practised with impunity on fruit trees, is not to be recommended. Hollies will bear such treatment if done at the proper time, and it will make them fruitful bearers, as I know by experience; but the shoots often die back at their points for a year or two, and make poor and scanty foliage, which deprives them of half their beauty. In root-pruning, therefore, only cut in their extreme points a little, also any strong tap roots that are pushing into the subsoil.

C.

DEUTZIAS FOR SMALL GARDENS.

For small gardens or the amateur's greenhouse, one of the most beautiful plants now in flower is *Deutzia gracilis*, a slender, twiggy, hardy, deciduous shrub. It makes a lovely pot plant for the cool greenhouse, and is very suitable for window culture. It is largely grown for Covent Garden Market, where large quantities of its flowers can be seen daily during the month of April. This plant is related to the *Philadelphus* of English gardens, of which *P. coronarius*, or the Mock Orange, is one of the sweetest and most useful shrubs we possess. All the *Deutzias* may be grafted upon the *Philadelphus*, but this is only necessary where fine plants are required for growing on cold uncongenial soils. The various species in cultivation, and the mode of treating them are as follows:—*Deutzia scabra* (Rough-leaved *Deutzia*) is a native of Japan; a hardy deciduous shrub, growing 6 ft. high, and blooming freely during May and June. It is not very particular as to the nature of the soil; it will flourish where a Currant tree will grow. *D. sanguinea*, which is useful for a wall or trellis, blooms in April, flowers red and very attractive. *D. corymbosa* has white flowers in corymbs; a shrub, grows from 3 ft. to 4 ft. high. Native of Kamaon. *D. brucniana* is a shrub 5 ft. high; flowers, white. Native of Kamaon. *D. staminea*.—Flowers, white, sweet-scented; height, from 3 ft. to 4 ft. Native of Nepal. *D. gracilis* (the Slender *Deutzia*) of Japan.—White; flowers in April. This is the dwarfiest and neatest-habited of all, and the most generally useful. If the *Deutzia* be well grown the previous season, it will be sure to bloom abundantly in April, and earlier in a warm greenhouse temperature. When it has ceased

flowering, cut away all the shoots that have bloomed. Keep the plants in a shady part of the greenhouse, and syringe them frequently to encourage a vigorous growth. Give plenty of air, and use the syringe freely till the middle of May, about which time the pots may be plunged in ashes in the open ground. In June slips of the new growth, taken off with a heel, strike rapidly in sand under a bell-glass, and when struck should be placed in small-sized pots for the winter, and be shifted as soon as they begin to grow in the spring. The only point of importance in their culture is always to make sure that the wood is well ripened in autumn. Water must be withheld as the growing season declines. Let the wood be of a fine brown colour before winter sets in, and the spring bloom will be satisfactory. If any plants be wintered while the wood is green they will either flower very thinly or not at all. All the *Deutzias* may be propagated in the same way as Currant and Gooseberry trees, by inserting ripe shoots round a large flower-pot in the autumn, and wintering them in a cool house or pit. After allowing them to grow one season without being disturbed, they may be planted separately into blooming pots, and the wood ripened out-of-doors in a warm situation, in the same manner as larger specimens are treated. *D. gracilis* and *D. scabra* are the most useful for the conservatory, as they can be forced with very little heat, and may be propagated to any extent with the least trouble by any amateur. Another very easy way to propagate them is by taking a good strong plant (after it has discontinued blooming, all the wood that has bloomed been cut out, and the new growth commenced), and turning it out of the pot about the middle of June, and planting it in the open garden. About the end of September, lift the plant, and split it up; place the three or four slips in a pot, as you would young *Geraniums*; winter in a cool greenhouse; let them have a season's growth, and in the autumn pot them off separately. They like a good soil and plenty of drainage. In summer regulate the growth of the young wood by pinching in, to cause the branches to become crowded with flowering spurs for the next season. When the growth begins to harden, withhold water, and expose the plants to the full glare of the sun, in order to ripen the wood perfectly. Success then becomes a certainty. *Decumaria barbara*, a hardy American shrub, belongs to the family of Mock Oranges, and is closely allied to the *Deutzia*. It produces flowers like those of the Lime, and is well adapted for forming a bowyer, the flowers being very sweet-scented, while the foliage is really beautiful.

HENRY TAYLOR.

Pencote, near Bedale.

ON THE GROWTH OF THE WILLOW.

(SALIX ALBA.)

It was a saying of the celebrated eremitical contemplator and lover of solitude, as well as promoter of monastic life, St. Bernard, that he had learned more from trees than men; and no doubt the naturalist with any poetical feeling in his temperament might well echo such a sentiment. But the physiological botanist, who looks about him in the woods and on the banks of streams, may also pick up some knowledge from studying the growth of trees; and even the common Willow (*Salix alba*) can show some very curious instances in its mode of growth and resuscitation. As a tree, its allotted life is but short in comparison with other deciduous trees, for it soon becomes hollow, and is easily upset by winds; but, says Mr. Lees, in "Science Gossip," it has powers of resuscitation which enable it to prolong or renew existence. The propagation of the Willow is easy enough, as a branch or stick, if planted, will grow; but after becoming hollow, and appearing to be an easy prey to the tooth of time or any wind that may blow, it is enabled by a remarkable process to send down roots from above, which anchoring in the soil, give the Willow a fresh hold upon life, and its protracted existence is thus secured. A silvery feature is given to a landscape where the waving Willows by the brook-side predominate, and are agitated by the wind. Even when denuded of their leaves, the willowy brook may still be traced, and the old pollards ranged along the bank, like giants with huge distorted heads, and bent towards the earth by the force of continued gales, make a characteristic feature not to be mistaken. I have noticed numerous old Willows on the banks of the river Teme in Worcestershire, which perhaps more than any other English river is bordered with Willows in every stage of age and decay, often forming very grotesque objects. As they are all pollarded by the farmers on whose land they grow, many of them form enormous heads on which in time a humus is deposited, and Mosses accumulate; thus affording a nidus for seeds and berries to rest upon and vegetate. In this manner epiphytes arise, and it is curious to observe seedling Oaks, Hawthorns, Alders, and Hazels, and sometimes *Sycamores* and *Asches*, besides smaller shrubs, growing upon and mixing their foliage with the old pollard Willows. An old Willow, with its family of colonists, among

German Iris
(*Iris germanica* var. *cerulea*).

Cut-leaved London Pride
(*Saxifraga umbrosa* var. *serratifolia*).

Double Wallflower (*Cheiranthus annuus grandiflorus flore-pleno*).

Menly Primrose (*Primula farinosa*).

Swiss Primrose (*Primula viscosa*).

Double Columbine
(*Aquilegia vulgaris flore-pleno*).

Mountain Valerian
(*Valeriana montana*).

Prostrate Speedwell (*Veronica prostrata*).

Canadian Violet (*Viola canadensis*).

Fennel-leaved Peony
(*Paeonia tenuifolia flore-pleno*).

Red Valerian (*Centranthus ruber*).

Thompson's Lily (*Lilium Thompsonianum*).

which are often many flowering plants upon its wide-distorted head, thus makes a very curious spectacle. As the Willow grows rapidly to maturity, its duration is proportionally short, and, shattered by winds and storms, it bends in a decrepit state over the streams on whose banks it grows—"stooping as if to drink," Cowper says—and becoming hollow with a still sprouting head, is easily overthrown. Fallen Willows often form rustic bridges, useful to the wanderer in crossing streams where there is no foot-path to aid his progress. Nature gives some compensation to the Willow for its short natural life by giving it means of resuscitation in several ways, and it clings to life with remarkable energy. Even if the trunk be broken and the head blown off, if the latter only retain the slightest hold upon the tree, and in its fall be supported by a neighbour, the head produces an abundant crop of branches, continuing to flourish notwithstanding its prostration. If a tree standing upon the river-bank, close to the water, get its roots exposed by the bank being washed away, these roots become leafy, and form so many fresh stems, with a bush of verdure as the process goes on. In this way the tree becomes duplicated; the upper portion above the bank, while the lower is below it, and partly in the water. Sometimes, while the bole of a Willow has from some cause become decayed, and utterly dead, the lower part next the ground retains vitality, throwing out a maze of shoots that surround and protect the decrepitated old rotting bole. Another way in which aged Willows are resuscitated, is by their power of sending down roots from the head within the hollow bole into the soil, thus giving fresh anchorage to the old tree; and when the decayed shell at last gives way to age and time, a scion of the demolished tree is left to occupy the ground, and to take the place of its departed sire. The Willow is thus invigorated with new life, and resists for many years the wintry gales that would otherwise have overthrown it. Modern writers have taken little note of this mode of growth, though it was remarked by Evelyn, in his "Silva," many years ago. He says:—"Trees will otherwise grow frequently out of the bole of the other; and some roots will penetrate through the whole length of the trunk, and, fastening in the very earth, they burst the including tree, as it has happened in Willows, where an Ash tree has sprung likely from some key or seed dropped upon the head of it." Evelyn's observation, however, rather applies to the roots of trees that have got fortuitously upon the heads of pollard Willows, and there vegetated, and not to the resuscitated growth of the Willow within itself, as I have here described. But Dr. Plot, in his "Natural History of Oxfordshire," has mentioned an Elm, "hollow as a drum, and decorticated at the base," which, as I have mentioned in the Willow, had "let down roots all the length of this empty case, and striking when they came to the earth from whence it derived nourishment, maintaining a flourishing top, and has till now passed for a little miracle." This curious Elm does not appear to have been noticed since Dr. Plot's time, and I fear is not now in existence. A few other trees throw down roots in this remarkable manner, but it is most obvious in the Willow.

Street Trees (see p. 435).—Allow me to refer any one interested in this really important subject to the beautiful avenues in Vevay, in Switzerland, consisting of various kinds of the Sorb or Service Tree. The brilliancy of their large scarlet fruit and the dazzling hues of their foliage are beyond description. There were two or three sorts in the avenues in question, but all were in fruit at the same time, and equally brilliant in the month of October. The clusters of white flowers, too, must be equally ornamental in the spring and summer. The foliage was abundant, and sufficient to afford a desirable shade to foot passengers.—A. L.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Tall Juniper.—It is stated that at Wardour Castle in Wiltshire there is a Juniper (*Juniperus communis*) 30 ft. high. In its wild state it rarely rises above the height of a shrub. I should be glad if any of the readers of *The Garden* could give me any information respecting the Juniper attaining the proportions of a tree.—T. J.

Abies Engelmannii.—In the grounds of Mr. Mercer, Bucks, we recently saw two fine specimens of the Engelmann Spruce. One was about 3 ft. high, and probably larger than Mr. Gray's at Boston, which we had supposed hitherto was the largest in cultivation. This beautiful Colorado Spruce seems well adapted to eastern coast culture, and we hope to see it become common.—"Gardeners' Monthly." [Is this tree in cultivation in England?]

Tree Roots Choking Drains.—A correspondent of a country paper says:—"A cure for this evil is coal-tar. I have had recourse to it with entire success. In using it I mixed it with sawdust to the consistency of ordinary building mortar. A layer of this was spread on the bottom of the drain; on this the drain-pipes were set, and then carefully covered all over with the tar-mortar. If the work be carefully performed, and the mortar applied in sufficient quantity—say $\frac{1}{2}$ in. thick all round—I can guarantee success."

PLATE XX.

THE RAMANAS ROSE OF JAPAN.

Drawn by H. HYDE.

With florists' Roses, provided labels do not get lost or misplaced, there is but little difficulty. If we are only sure that a particular plant is Isabella Sprunt or Maréchal Niel, we do not lose sight of that fact; but when we come to speak of Roses in their natural state as species, we are at once surrounded by difficulties. The very quality that makes the Rose so valuable to florists—its tendency to sport into new forms—is that which makes the plant so uncertain in the wild state. In the whole of Britain, according to Bentham, there are only five species of native Roses, while other botanists hesitate between nineteen and twenty species. We mention this to show that it is not surprising, when we come to examine an interesting Japanese Rose, that we should be in doubt what botanical name to give it. But first as to the Rose itself, which we met with several years ago in the garden of Mr. James Hogg, to whom it had been sent from Japan. It being quite unlike any other Rose in our garden, we were much pleased to receive in the course of a few months specimens from Mr. Hogg, and also from Mr. John Saul, of Washington—and no Roses in our little collection afford us more pleasure than these do. Those who think a Rose not worth looking at unless it is as double as a Drumhead Cabbage will hardly consider this single Rose desirable, but those who can see beauty in a plant, even if it

Ripe Fruit of *Rosa rugosa alba* (natural size).

have not double flowers, will regard it as a fine ornamental shrub. This Japanese Rose grows from 2 ft. to 3 ft. high, and with its numerous branches forms a very compact bush. Its young stems are very downy, and thickly beset with sharp but weak prickles, of very unequal size. The stems being short-jointed, the leaves are brought very closely together, and make a dense mass of foliage; the leaves are about 4 in. long, with usually seven elliptical leaflets, which are light-coloured on the under surface, being covered with a down of dense somewhat glandular hairs, and conspicuously veined; the upper surface, on the contrary, is perfectly smooth, somewhat shining, and of a very dark green; the surface is strongly marked by depressions corresponding to the veins so prominent below, making the leaves appear to be plaited; the stipules are comparatively small. Taken as a shrub, without reference to its flowers, its dense habit, and abundance and richness of its foliage, make it a most pleasing object. While other plants in the same bed have been attacked by the many insects that infest Roses, the foliage of this has passed into August without a blemish. The flowers are produced in clusters at the end of the current season's shoots on short downy stalks, and have an agreeable wild Rose fragrance. The fruit or "hip" is spherical, or somewhat depressed, about three-quarters of an inch in depth, of a fine red when ripe, and looking much like a Crab Apple. The difficulty of applying botanical names to wild Roses has been already alluded to; the present one may be found in books as *Rosa rugosa*, *R. Fortunei*, and *R. Regeana*, all evidently the same thing, varying as to the tendency of the flowers to become double; of these names *Rosa rugosa*,

THE RAMANAS ROSE (*ROSA RUGOSA ALBA*)

the "rough Rose," is the oldest; but some botanists say that this is the same as the Kamtschatka Rose, which is a doubtful species. In all this confusion we were glad to come across a good name for our Japan Rose. According to Thunberg, who first brought the plant into notice, it is called by the Japanese Ramana, a name which will serve to designate the Rose, until botanists have satisfactorily cleared up the matter. We have both the ordinary form with white flowers, and a red-flowered one. French works mention a double variety, and our plants often produce flowers with several extra petals. This Rose is a capital subject for experiments in hybridizing; if by this means varieties could be obtained, in which the fine flowers of the Remontants and others were united with the compact habit and robust foliage, and healthy vigour of this, it would be a great step in Rose culture.—"American Agriculturist." [Our figure of this Rose was prepared from a drawing made at Mr. Ware's Hale Farm Nursery, Tottenham, where there is a good stock of it. It may also be found in other nurseries in the neighbourhood of London.]

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Flower Garden.—Those, even in the most favoured southern parts of the kingdom, who have exercised the necessary caution in not beginning to bed-out too soon, will see the advantage in having done so, for even such comparatively cold-resisting plants as Calceolarias have hitherto been better indoors than out in the beds; a commencement should, however, now be made with them, following with Pelargoniums, Verbenas, and Lobelias; the more tender subjects, such as Ageratums and Heliotropes, should be kept indoors a little longer. Even in the case of Calceolarias and similar plants, should there be an appearance of cold cutting winds, some protection should be given; the old method of sticking Laurel, Spruce, or other ever-green branches round the beds and in amongst the plants will be of much benefit, but care must be taken to insert them deeply in the ground so as to prevent wind-waving; for, should this occur, they will do more injury than good by chafing the plants. Coleuses, Iresines, and Alternantheras should by no means be trusted out until quite the end of the month or beginning of next, as the occurrence of a few hot days is no guarantee of a continuance of warm weather, and, even should no absolute frost ensue, a temperature anything approaching it would give them a check that would prevent any progress being made for some time. Annual Stocks that have been sown in small pots some time back for turning out may now be planted; but Asters had better be kept under cover another week. In the North planting should be deferred ten days later than in the South. Do not keep Dahlias too long in small pots, for if the roots be allowed to get stunted they will be long in commencing growth after being planted out, a remark which more especially applies to such as have been struck from cuttings; where necessary, these should have pots large enough to keep them growing freely until the end of the month, which is early enough for them to be planted. Large roots of these that have not yet been divided should now be cut up and put in 6-in. or 7-in. pots, according to the size of the pieces, leaving a strong shoot to each; place them in a cold pit or frame, with plenty of air. Roses should be cleared over frequently, in order to destroy the Rose maggot which lies close over in the leaves; if this pest be not killed, few of the flowers will escape being eaten by it. The trees should be regularly syringed before aphides get to a head, or these will be difficult to deal with; if they are numerous, Tobacco or Quassia water should first be used, letting it dry on, and using clean water at intervals afterwards.

Kitchen Garden.—More Peas should now be sown, and if tall kinds be used give them plenty of room, for close sowing defeats the object in view. In the case of root crops it results in a large proportion of top and a comparative deficiency of root growth. In that of Peas and Beans its effects are a preponderance of haulm with small pods. In that of the Brassica family quantities of leaves with little that is usable; however good the soil may be, crops of all kinds must have room in order to afford them a sufficiency of light and air; in rich, heavily-manured land, it is necessary to sow and plant further apart than in poor ground, as the greater capabilities of the soil to induce vigorous growth, the more room will be requisite. Of Broad Beans another sowing may now be made, although the produce of such as are put in now, except where the land is particularly adapted for their growth, will not be equal in quantity to that of the earlier sowings. A little more Turnip seed should be sown in some moist situations, which during the hot summer months is better than a dry one. The

principal crop of Beet should now be sown, and more Spinach, Lettuces, Radishes, Mustard, and Cress should also be put in; for these the soil should be well enriched, as during hot weather everything has a greater disposition to run to seed than when it is cold, and this is best prevented by using plenty of manure and giving a sufficiency of room. A little more Cabbage, Veitch's Autumn Cauliflower, and late spring Broccoli should likewise now be sown. In the case of Celery, the disposition to run to seed is much greater in some sorts than in others. By some hollow or pipy Celery is attributed to the system of cultivation pursued, such as heavy applications of manure, or the kind of manure employed; but this I believe to be a mistake. Where Celery is not subjected to unnecessary checks in transplanting, where it does not suffer through an insufficient supply of water, and where a really good variety is grown and fairly managed, even if sown as early as February, it will not show any inclination to run to seed until the end of March or the beginning of April in the following year, but where Celery is wanted until the time just mentioned, in case of any mishap a little seed should be put in now. Some of the early sown Celery should now or very soon be planted out; where the land on which it is to grow is of a dry, hot, sandy nature, much more manure will be required than where it is of a heavy, cooler character, and for the former cool manure is better than that procured from stables; where the latter is used, it is by no means necessary that it should be rotten to the extent often urged. Some of the best Celery I ever grew or saw was obtained by means of stable manure that was quite fresh, and that had not lain together sufficiently long to ferment. If manure be at hand, get the trenches for the whole crop prepared forthwith. In that case not only will the ground be better fitted to receive the plants by lying for a time before planting, but if the ridges be finished at once, they can be sown with Lettuces or Spinach, which are about the only crops that do not interfere with the growth of the Celery, and the earlier they are sown now the better. The practice of planting Celery or Broccoli alternately between rows of Peas I do not recommend, as unless space is sacrificed in planting the rows far apart, the Celery always suffers both by being shaded and also by the ground being trodden on while the Peas are gathered. If space be limited double or treble rows of Celery may be put in for the earliest crops that are likely to be used in the autumn before hard weather sets in. The plants in this case should stand a foot apart in each row, with as much space between the rows. For this arrangement the trenches should be prepared about 3 ft. or 4 ft. wide, according to the number of rows intended to be planted in them, but for Celery that is to stand the winter—except on dry soils, where double rows may be used—single rows are much the best; in the latter case not only will the produce be larger, but it will keep better, will be much easier to earth up, and will admit of being protected from frost with less difficulty, and the weight on a given space in single rows is nearly as much, for it need not be planted above 9 in. apart, and the trenches will do much better nearer together. In heavy land that is at all wet the trenches for the winter crops should not be nearly so deep as where the soil is drier. In old gardens that have been heavily manured, and especially where much leaf-mould or other vegetable matter has been annually dug in, a portion of new soil mixed with the manure will be found much better than the latter alone. A good sprinkling of salt dug in with the manure will also be found to be an improvement, as Celery, in common with other marine plants, is naturally benefited by salt. The early-sown plants of Cabbage, Cauliflowers, and Brussels Sprouts are unusually backward this season, consequent upon the protracted cold weather. A good crop of the last-named is so much dependent upon early planting that, as soon as the plants are sufficiently large to handle they should at once be put out where they are intended to be grown; the natural erect habit of this vegetable often induces its being planted too close; but, with this, as with all others, nothing is gained by an insufficiency of room, as the produce of each individual plant is thereby limited, and, should a very severe winter ensue, crowded crops are frequently completely destroyed, while those grown under conditions that afford them sufficient air and light escape with little injury. The nature, and rich or poor condition of the soil, should in all cases be considered when planting these vegetables, for, where the land has been well prepared, the plants will grow to double the size than if it be in a poor condition; place them not less than 2 ft. 6 in. apart and the same between the rows. Some of the early-sown Cauliflowers should also be planted as soon as sufficiently large, except in the most suitable soil the produce of these spring-sown plants is not nearly equal to those sown in the autumn, being deficient in the white compact heads generally seen in the latter, but they thrive much better if transplanted from the seed-bed to their allotted place when quite small, as then they receive less check in the removal. In all cases the practice I have previously recommended of putting about half-a-

handful of soot and lime to each plant at the time of planting will repay the trouble, especially on land where the Cabbage family is liable to club, for, independent of its acting as an antidote to this disease, when carefully applied, its effects as a manure are worth the cost. Lettuces should also be planted whilst small, removing them with as little breakage of the roots as possible, for on this and a rich soil with plenty of water in dry weather depend their quality and ability to grow to a full size. Do not leave anything that is intended hereafter to be planted out to remain crowded in the seed-bed; thin out all Cabbages, Cauliflowers, Broccoli, and Kale, so as to allow them to stand from 4 in. to 6 in. apart, according to the length of time that is likely to intervene before they are planted.

Fruit Garden.—Where Apricot and Cherry trees are affected with the grubs that do so much damage, these pests should be diligently destroyed by crushing them within the leaves where they take shelter. Immediately there is any appearance of aphides on Peaches or Nectarines, they should be syringed with Tobacco or Quassia water; a good washing will generally be found sufficient, if the operation be performed before the trees have become much infested. After this time they should be regularly washed twice or three times a week; where many are grown, the garden engine is much to be preferred. There is no other means of keeping the leaves healthy, and without this attention the fruit cannot be grown to anything approaching perfection. Thin a portion of the fruit, and remove superabundant shoots.

Stove and Greenhouse Ferns.

The rapid growth these are now making will necessitate a free use of the watering pot. If the drainage be effective and the soil porous, it is almost impossible to give them too much water at the root during the next few months. Tree Ferns especially require the greatest attention while forming their young fronds; in fact, during their growing state it is a safe plan to pour a quantity of water down their stems at least once a day, for if allowed to become at all dry the beauty of the plants will be spoiled for the rest of the season. Where these are confined to small tubs or have but limited root-space, manure-water will be found of the greatest assistance in keeping them in a healthy condition. It however more generally occurs that the growth of Tree Ferns is too rampant for the positions assigned them, and the best way to check this tendency to over-luxuriance is by removing any of the fronds that can be spared without detracting too much from the beauty of the plants. Fly well the syringe, so as to thoroughly moisten the floor, stages, and other available surface, both morning and evening, whenever the weather is bright and clear. Ferns delight in atmospheric moisture; but in order to secure strong firm growth, an abundance of light and air must be afforded them. If the fronds be required for cutting, the plants should be kept well up to the glass, and only receive shade during the hottest and brightest part of the day. This will thicken and harden the tender leaflets, and cause them to last double the time they would under ordinary treatment. The fronds of that old favourite for cutting purposes, *Adiantum cuneatum*, are much increased in value by being grown in a light airy house, as they become ripe and firm, and of a more pleasing pale green colour. Few are more highly prized for associating with flowers in table decoration; and, in order to induce them to droop gracefully, the pots containing the plants should be turned upside down and suspended for a day or two, that the fronds may be made to curve in the proper direction. Many of the *Davallias* are very lasting in a cut state, and are deserving of extensive cultivation for that purpose. The very elegant *D. tenuifolia* is perhaps the handsomest and most durable, but it is unfortunately of slow growth, and therefore, to supply fronds in quantity, a number of plants must be cultivated. *D. bullata* lasts longer when cut than any other Fern with which I am acquainted, and is, on account of its minute size, admirably adapted for using with *Gloxinias* or other short-stemmed flowers. Next to *Adiantums* comes the *Onychium lucidum*, its fine feathery appearance rendering it a particularly suitable companion to flowers in vases. This should be grown extensively where Ferns are in much request for cutting, as it bears the treatment much better than most others. A light, airy position is necessary for its successful growth, and as it is as near hardy as possible, any cool house will suit its requirements.

Hardy and Half-hardy Ferns.

Now is a good time for planting out any of the latter that have been wintered in pots, that they may make their growth in the positions assigned them, and by that means establish themselves well by the autumn, when a slight covering of dry leaves, or some other non-conducting material thrown over them will make them tolerably safe for the winter. Any re-arrangement of kinds that have outgrown their positions, or any alterations that may be thought neces-

sary or desirable, involving the removal of plants, should be carried out at once, as most kinds transplant better now than at any other season, provided they are not too much advanced in growth. Where there is any deficiency of wild flowers in connection with the hardy Fernery, the present is the most favourable time of the whole year for remedying the defect, as they can be seen and collected with much greater ease now they are blooming than they can at any other season. In addition to wild flowers, many cultivated kinds are equally suitable for the above purpose, some of which have been previously enumerated.

Conservatories.

Heaths.—Free-growing kinds of these, as *Erica Willmoreana*, *hyemalis*, *melanthera*, and others of that class that were cut back some time ago, and placed in close houses or pits to induce them to break again, should now have more air, which will strengthen the young wood, and help to ward off attacks of mildew, to which the two former are very subject if kept long in a confined atmosphere. The above, with others of similar habit, do well at this season, when treated the same as *Eparis*es, as each requires the same kind of treatment. Where there is the convenience of a house or pit, they may with much advantage be gently syringed overhead, and have the lights closed early in the evening till their growth is more complete, after which an abundance of air is necessary both day and night to harden and mature the young wood. In their present stage, and for several months to come, shade is of the utmost importance to both *Heaths* and *Eparis*es, and where the pit or house has a suitable aspect, it will be found to agree with them much better than covering the glass. When *Eparis*es are exposed to bright light while their growth is young and soft, the tips of the shoots become brown and discoloured, which detracts much from their appearance, besides hardening the wood and keeping it short and stunted. Any of the above that have not yet been re-potted should at once be attended to, as the roots are just now in an active state, and require fresh soil to feed on if a vigorous growth be desired. Tough, fibry peat with a fair proportion of sharp silver sand should be used, and in potting give only a moderate shift that the same be repeated again next season, which is a more preferable course than affording them a large body of fresh soil at any one time. In potting, use the peat in a healthy moist state, and ram it as firm as possible by using a properly-prepared potting-stick for the purpose.

Dentizias that have now done blooming should have the old wood cut out, after which the plants should be placed in a close pit or frame, where they can get a little heat to encourage the growth of the young shoots now showing round their collars. If in small pots, a shift into others will be of the utmost benefit in assisting them to make strong shoots, which, if well ripened, are sure to produce a fine head of bloom. If intended for very early forcing, it is better to let a portion of the plants complete their growth without cutting out any of the wood, as then they ripen off sooner and produce their flowers earlier. Cuttings of the young half-ripe wood root freely now if placed in a little heat; and as the *Dentizia* is such an indispensable plant for forcing, a few should be struck every year to replace those that become starved or worn out from old age or otherwise. *Dentizias* may be readily divided, and succeed well in that way if grown on in a little heat till they become re-established. The double variety, *D. crenata flore-pleno*, although it will not force so readily as the old favourite, is nevertheless most valuable later in the season as a pot plant for conservatory decoration, and when placed out in order to show off its numerous racemes of flowers which it produces so freely up the entire length of its stems, it is exceedingly effective. This should always be cut down after it has done blooming, when it will send up fresh shoots at least 3 ft. high, and strong in proportion.

Libonia floribunda is invaluable for winter work, and cuttings should be put in at once to afford time to get them a serviceable size before the growing season is over. Where size is desired, any old plants now going out of bloom should have their shoots shortened well back, and be then placed in gentle heat to give them a start, after which they should be transferred to cold pits or frames, where they can be fully exposed during the summer whenever the weather is favourable. The secret of success in flowering these successfully is to get the young growth thoroughly ripened, which is impossible where they are treated under glass with greenhouse plants. When well grown and bloomed, and associated with the *Serriogaphis* in forming groups to furnish gardeners, they are exceedingly effective, as the yellowish shade of their flowers shows in pleasing contrast with the bright scarlet of the above, while the growth and habit of both plants render them suitable companions. *L. penrhaisiensis*, a cross between the *Serriogaphis* and *L. floribunda*, is likewise a very desirable plant to cultivate, and flowers the whole of the winter in an ordinary greenhouse temperature. This partakes more of the

character of the *Soricographis* as regards foliage and general appearances, while the bloom is intermediate between the two parents.

Schizostylis should be largely grown wherever a supply of winter-blooming plants has to be kept up. Those who are fortunate enough to have a few plants of these ought at once to set about dividing them, for the purpose of planting them out in light rich soil, to be lifted again in the autumn; so treated, they increase rapidly, and flower with much more strength and freedom than if confined to pots during the summer, where they have an insufficiency of root-room, and perhaps frequently suffer from want of water. When this occurs, either in pots or planted out, red spider is sure to attack them and cripple their growth. To prevent this pest effecting a lodgment, the plants should be frequently syringed during dry weather, and if the ground around their roots be mulched over, it will keep them in a more uniform state as to moisture. If grown freely in this way, their leaves attain the size of small *Irises*, and the flowers nearly equal those of *Gladioli*, which they closely resemble. For cutting, there are few things more generally useful, as they are very effective and last long in condition. If planted in warm, sheltered positions, part of the stock may remain in the ground for the above purpose, as they are quite hardy, and will thus afford a succession to those treated under glass.

Spiræas that have done blooming must be kept well supplied with water, that they may finish their growth and develop fresh crowns for blooming again next season. Where it is desirable to increase the stock of these, it may readily be done by dividing the crowns, and then re-potting them again or planting them out where they can be well supplied with water, of which they can never have too much as long as their leaves continue on them, and they are making the least growth. If planted out they should be placed in slight trenches in which they can be more readily watered during the summer, and if well attended to in this way the situation cannot well be too sunny or open. *S. palmata* will be much sought after for forcing as soon as it becomes more plentiful, but unfortunately it is very slow of increase, and is therefore not likely to be over-abundant for some time. Solomon's Seal, so useful for forcing purposes, should now be divided and planted out in good rich soil, where it will make fine roots for lifting and re-potting in the autumn.

Chrysanthemums.—Early-struck plants of these should be regularly shifted on as they fill their pots with roots, so as to prevent any check to their growth, otherwise they soon lose their lower leaves and become shabby. Cuttings struck now will make useful plants if liberally treated during the summer, and will be found quite large enough for ordinary purposes. Being gross feeders pot them in a rich, stiff soil, consisting of about a fifth part of sweet, rotten manure to four parts of good, fresh, fibry loam, rather inclined to adhesiveness than otherwise. In this they will make firm, short-jointed growth, and retain their leaves well down to the pot, a point of much consideration in the cultivation of these most useful plants, and without which they present but a very poor appearance. To keep them in this desirable state, they must never be allowed to suffer from want of water, and as soon as the pots get well filled with roots, liquid manure, if not too strong, will be found of the greatest assistance to them. Before plunging them out in an open border, see that they are clear of aphides, or the young growth will be crippled as it is emerging from the stems into leaf. A sunny situation suits them best, provided it be not too much exposed to the wind, in which case the plants would be liable to injury as soon as their branches were a foot long, as at that period of their growth they easily break out at the joints. Choose a firm, hard bottom on which to grow them, that it may be impenetrable to worms, which are otherwise sure to interfere considerably with the drainage, from the want of which *Chrysanthemums* always suffer. To shade the pots from the rays of the sun, and prevent the too rapid desiccation of roots by currents of air acting continuously on their sides, they should be well packed round with ashes, or some other close-plunging material that will answer the same purpose. *Chrysanthemum frutescens* deserves to be more frequently cultivated than it is, for it may be had in bloom during nearly the entire year, and if specially prepared by stopping the ends of the shoots during the summer, it may be had in fine condition through the whole of the winter, flowering freely in the ordinary temperature of a greenhouse. It has beautifully divided foliage, of a light glaucous green colour, that contrasts with its pure white flowers to the best advantage. With such plants as *Salvias*, *Pointsettias*, and others of that class, it is exceedingly effective, and will be found one of the most useful plants during the winter season. Cuttings put in now, and treated much after the manner recommended for the common *Chrysanthemum*, may be grown to a large size by the autumn, but as they are very susceptible of injury, they should be housed before the frosts come.

Lantanas are not nearly so much grown in pots as their merits deserve, now that there are so many fine, large, free-flowering varieties suitable for the purpose, with large *Verbena*-like heads of bloom. *Lantanas* are easily raised from seed, and any sown now and pushed on in heat will make flowering plants by the end of July. Those saved through the winter may be grown to a large size the following year, and be had in bloom the whole of the summer months.

Kalosanthes.—These will now be pushing up their flower-heads, which from their great weight require support, or they soon droop over. Keep them well up to the light to prevent them being drawn, and if confined to small pots some weight to prevent them being drawn, and useful in keeping their leaves a rich dark green colour, without which the plants lose much of their attractiveness. The present is a good time for putting in cuttings of these to grow on for another year. Place them in sandy soil, and stand them in some light dry position till they root.—J. SHEPPARD, *Woolverstone Park*.

Orcchids.

See that all the plants are firm in the pots, and put a stick to any that may be loose, for if the plants be not firm they do not root well. The best stick for Orchids is the cane of the Bamboo, which is to be procured in bundles at a low rate at most of the leading London nurseries; it is very slow to decay, and, when decayed, it does not breed fungus like sticks made of common deal. It is, however, desirable to use as few as possible, one or two being sufficient for most plants, and these should be drawn out as soon as the plants are firmly rooted, if not required to support the top. Be careful that the growing plants in baskets and on blocks do not lack water; examine them every morning before the sun is strong, dipping those plants which require water in a tub or large flower-pot with a cemented bottom prepared for the purpose. While the plants are being dipped search for wood-lice, &c., which are almost certain to come to the surface after immersion. Let the plants drain well before hanging them up, so that no drip falls on those on the stages underneath. Never dip the plants in the tank containing the water used for watering. Do not employ the syringe as the means for watering the baskets, &c., for one can never know when they are wet or dry, and the plants that do not need water have to take their chance with others that do; besides, all miss the requisite examination and handling which is an important part of Orchid growing, and the drip from the syringed plants would be ruinous to those underneath. Attend to air and shade as previously recommended, and do not relax in any efforts to keep down insects, the present time being the most important for that operation. A syringe with a fine spray jet may now be used every morning, taking great care that the water does not get into the young growth. The plants should be syringed so as to make the spray like a heavy dew, and not until they drip. The East Indian Orchids should not be syringed more than two-thirds of the way up, leaving the middle leaves dry. Syringing, if not carefully performed, had better be confined to the back walls, underneath the stages, &c. All the houses will now bear a slight increase of temperature, but any resting plants should not be subjected to it, but placed in the coolest part of the house, or in another that is dry and cool. The temperatures for Orchids during the month of May should be:—warm house, from 70° to 75° by day, and 65° at night; intermediate or Cattleya house, from 65° to 70° by day, and 60° at night; *Odontoglossum* or cool house, from 60° to 65° by day, and 55° at night. The higher day temperatures are for sunny days. Keep the atmosphere of the houses sufficiently charged with moisture by throwing water under the stages, &c. The amateur having but one house should heat it as an intermediate house.—JAMES O'BRIEN.

Floral Decorations for May.

Flowers, for decorative purposes, are much more numerous now than in April, the new arrivals more than compensating for the loss of *Cyclamens*, *Roman Hyacinths*, *Camellias*, and other valuable blooms, which have been so useful to us during the earlier months of the year. Perhaps the most noteworthy addition to our list of new plants suitable for forcing is the brilliant crimson *Spiræa palmata*. This and hydrocephalic *Hydrangea* have been making a grand display during the last few days in Covent Garden Market, while *Pelargoniums* of almost every shade in crimson, pinks, mauves, and whites are "gorgeously arrayed" with blooms. *Lilacs* and *Mock Oranges* are now opening their buds, and *Dentizias*, *Azaleas*, and *Rhododendrons* in our shrubberies will quickly follow them. It is very fortunate that *Dielytra* and *Solomon's Seal* blossom at the same season, for it would be difficult to name any other two flowers which would produce a more elegant display in a large trumpet-shaped vase than three or four sprays of each of these plants tastefully arranged. There is a harmony of form in both having drooping blooms, and there is a contrast of colour between the respective flowers and also between the leaf of the *Polygonatum* and the blossom of the *Dielytra*.

Wistaria forms a pretty "droop" around the edge of a tall vase, but it must be wired properly, and care must be taken that its newly-cut stalk is in the water, or it quickly fades. It is difficult now to get hard, lasting fronds of Maiden-hair or of any other Fern. The young leaves of the Cow Parsnip or Hogweed, which may be found in almost every hedgerow, form an excellent substitute for Fern-fronds; and many other wild umbelliferous plants might doubtless be used with good effect. Wild Grasses are also now coming on, and have already supplied very graceful contributions to several vases.

Blue—Cineraria, Gentianella, Iris, Myosotis, Nemophila, Pansy, Wild Hyacinth.

Purple—Anemone, Cineraria, Dog Violet, Heliotrope, Iris, Lilac, Pansy, Tulip.

White—Cineraria, Heath, Iris, Pansy, Tulip, Wistaria.

Pink—Azalea, Begonia, Bouvardia, Carnation, Dielytra, Fancy Pelargonium, Fuchsia, Heath, Hydrangea, Oleander, Rhodanthe, Rose, Tulip, Zonal Pelargonium.

Crimson—Bouvardia, Cydonia japonica, Fuchsia, Japan Primrose, Polyanthus, Rose, Spiraea, Wild Orchis.

Scarlet—Anemone, Bouvardia, Carnation, Euphorbia, Ranunculus, Tropeolum, Tulip, Zonal Pelargonium.

Orange—Carnation, Cowslip, Narcissus, Polyanthus, Rose, Tulip.

Yellow—Alyssum, Azalea, Broom, Calceolaria, Coronilla, Cowslip, Genista, Globe-flower, Gorse, Iris, Lachenalia, Narcissus, Polyanthus, Primrose, Rose, Tulip.

White—Alyssum, Anemone, Aponogeton, Arabis, Arum, Azalea, Begonia, Bouvardia, Carnation, Chinese Primrose, Deutzia, Eucharis, Fancy Pelargonium, Gardenia, Guelder Rose, Heath, Laurustinus, Laurel, Lilac, Lily of the Valley, Mock Orange, Myosotis, Narcissus, Pink, Rhodanthe, Snowflake, Solomon's Seal, Spiraea, Stephanotis, Tulip, Woodruff.

W. T. T.

Roses.

Roses in pots that have been forced during the winter months should not be left to take care of themselves in summer; on the contrary, they require to be carefully pruned, in order to induce them to make good young growth by the autumn. In cases in which the plants have got much drawn and unsightly, if the plants be well rooted, they may be shortened well back. Examine also the drainage, and top-dress with some good fibry loam and manure, making the surface very firm, so as to prevent evaporation. After top-dressing, select an open piece of ground, and on this make a bed of ashes to keep down worms. On this ash-bed place the plants in such a way that air can pass both through and around them. They will need no manure-water until they have thoroughly commenced their second growth; but water them when necessary with soft or pond water. If the water be hard, it should always be exposed in an open tank or tub for twenty-four hours before it is used.—H. G.

Trees and Shrubs.

All those plantations that were formed during the past season should be carefully examined to see whether any of the trees have been blown out of the perpendicular; should any have so suffered, tread them up firmly and place a turf on the leeward side. Trees that are tied to stakes should not be allowed to have the ligatures too tight, or the bark rubbed or injured. Continue the planting of evergreen trees and shrubs during the present favourable weather. Repair wood rides and roads wherever necessary. Clean out ditches and culverts that are choked up with leaves and other refuse. Make secure all hedges, gates, and stiles from the inroads of cattle. The hedges should have been trimmed or pleached by this time. Young hedges should be kept clear of weeds for the first or second year after planting by means of hoeing; pointing them over with a spade once during the summer will be found sufficient attention afterwards. Thin plantations without delay wherever they are in an overcrowded state. Mark all Oak timber for the approaching bark-stripping season. In the nursery finish the planting of deciduous subjects, and continue the planting of evergreens into nursery rows. Rearrange and regulate ornamental evergreen tree and shrub borders. Prepare the ground and begin to sow Conifer seeds whenever the land is in working order. Remove the weeds from seedling-beds by hand-picking, and keep the Dutch hoe at work amongst transplanted trees and shrubs in nursery rows. All the spare ground intended for a green or root crop should receive a heavy dressing of manure, compost, or lime, and be well trenched in.—G. B., *Longleat*.

Orchard Houses.

TREES in a cool house having by this time fairly developed their leaves and fruit, the winter pruning should be supplemented by removing all superfluous shoots (of which, in vigorous and healthy trees, some will be left), and the fruit-bearing wood for the next season prepared. It is too early to thin the fruit, which, as a general rule, should be

left until the stoning has been completed; but a general estimate can be formed of the quantity of fruit to be allowed, and the final pruning should be subordinated to this end. In old trees many fruit-bearing shoots must be sacrificed by thinning out clusters of them, and pinching the more vigorous, to preserve a proper balance; there is no danger in the last operation when the trees are under glass. Plenty of air must be given on warm and sunny days, and the trees watered according to the weather. During cold and frosty winds, close all the ventilators to windward. A careful watch must be kept for the appearance of aphid, from which few Peach houses are entirely free: if taken in time, it can be effectually destroyed by fumigation and washing.—R.

Hardy Fruits.

Peaches and Nectarines claim the first consideration, and must be finished disbudding forthwith. Green or black fly invariably puts in an appearance before or about this time, and directly it is seen steps for their eradication should be taken, for if left but a few days they increase like magic, and the work of extermination is consequently much more difficult. I have used Tobacco-powder, applied through a flour-dredger, whilst the dew was on the trees, with good results: but the cheapest remedy, if taken before the fly has got the upper hand, is to syringe the trees with soap-suds once a week; I do this as a preventive, and am seldom much troubled with the pest. As the weather becomes warmer, and after the fruit has been thinned and has begun to swell, I give the trees frequent washings with the hose or garden engine; if I meet with troublesome, the Gishurst Compound, used at the rate of from two to three ounces per gallon of water, and syringed over the trees, is a certain cure. Apricots have set thickly on the uppermost branches, but the lower ones are quite bare of fruit, so that all the thinning required will be to relieve the clusters by giving each fruit plenty of room in which to swell. In previous years I have been much pestered with the soft brown scale on Apricots, but have now dislodged it by winter dressing the whole of the trees with a composition of Gishurst and soot, also colouring the walls with a similar mixture. Early Cherries have set their fruit in profusion; and Morellos, now in full bloom, promise to be a heavy crop. The above-named remedies for fly should now be applied to these, as they are peculiarly liable to their attacks. Pears on south and west walls will now require to have the breastwood shortened back to two or three eyes or joints, and any branches that are required to fill blank spaces should be at once trained into position. The earliest fruit is also ready to thin, and in this respect Pears are as deserving of at least as much attention as Apricots or Peaches. Standard and pyramidal trees should not yet be pinched, as the young growths in a measure assist to guard the fruit from frost; as soon as danger in this respect is over, pinch them into the desired form. Plums on walls have also already made immense growth, and should now be shortened back. The fruit of most kinds having set in clusters, will shortly require to be thinned—at all events, those intended to be grown for dessert merit this attention; culinary kinds are not of so much importance, and if time cannot be spared they may be left to take their chance, though it be at the risk of having a very poor crop next year, for a superabundance one year is sure to end in failure the next. Grafts should be looked over, and if the clay be cracked, sprinkle them with water, and rub over to make them air-tight; some of the earliest grafts that have started into growth may require the clay removed and the ligatures slackened. Syringe the grafts occasionally when the weather is warm and dry, and keep the suckers rubbed off the stock as they are produced. If newly planted trees were mulched at the time of planting, there having been so much rain, watering will not be required for a long time, but it will be advisable to sprinkle the trees overhead on warm evenings. Strawberries are throwing up their flower-stems, and should the weather prove dry, they ought to have a thorough drenching of water as soon as the fruit is set—of course it is presumed that mulching has been applied long ago. Forced Strawberry plants should at once be planted out, as before recommended, in order to produce runners for next year.—W. WILDSMITH, *Heckfield*.

African Species of Coffee Plants.—A paper "On the African species of the genus *Coffea*," by W. P. Hiern, was read at a late meeting of the Linnean Society. The author describes fifteen species, eight of which are new. The Liberian or Monrovia Coffee, which has, from the flowers not having been seen, been considered a variety of *C. arabica*, is made a distinct species, and described under the name of *C. liberica*. The ordinary Coffee, *C. arabica*, is stated to be a native of Abyssinia, Central Africa, and Angola; it possesses several varieties in the size, shape, and colour of the berries.

THE FLOWER GARDEN.

MELIANTHUS MAJOR.

THIS is unquestionably one of the most effective half-hardy plants which we possess for the summer decoration of our flower gardens. With its finely-cut, large, glaucous foliage contrasting so effectively with the general types of vegetation, and being a plant of the easiest cultivation, the *Melanthus* has for years become a general favourite in all arrangements in which an attempt at sub-tropical gardening has been made. The best means to pursue as regards propagation is by seed, from which it is freely produced, as plants that are raised from seed early in the season make famous growth by planting-out time, and attain by mid-summer a height of from 3 ft. to 4 ft. When it is desirable to have larger plants by planting-out time, it is advisable to sow the seeds in autumn and keep them growing throughout the winter, and a stronger and earlier development will be the result. Until the present system called into vogue the nobler forms of vegetation for the embellishment of our summer gardens the *Melanthus* was favoured with a place in the greenhouse, and even now a well-grown specimen is by no means a despicable object in a conservatory. The *Melanthus* is all but hardy, when planted out upon a well-drained subsoil, in the south and western districts, in sheltered

Melanthus major.

nooks, and although the stems may be cut down by frost, the roots will survive and push up in spring; but like *Cannas*, *Arundo Donax* var. *versicolor*, and similar plants, I find as a general rule, more particularly in wet, hard winters, that they are not to be depended upon, even when carefully mulched and otherwise protected, frequently suffering from accumulated damp. It is far safer to lift the roots and store them away under the stage of a cool house or shed, where the temperature is but a few degrees above zero. When seed can be depended on as true, there is little gain or necessity for resorting to any other means of providing stock. On referring to my notebook of the spring of 1875, I found that I had sown eight packets of seed, purchased from various firms, the majority of which did not vegetate, and such plants as were produced were in every instance those of *M. minor*; this spring I again sowed six packets with the same unfortunate results. My misfortune for two seasons in vegetating the seed of *Melanthus major* has prompted me to offer these few remarks, in the hope that seedsmen may examine for themselves the seeds of *M. minor* and *M. major* before sending them out to the public, for the difference between them is so apparent that the most inexperienced may at once detect it. G. WESTLAND.

which Daffodils in some places grow. There is a copse on this estate where three cartloads (taken up, as I imagine "Forester's" were, in clumps with earth attached to them) would be about as much missed as three buckets of water taken from the sea. In another wood here are scores of cartloads of the beautiful wild Hyacinth, and in another many cartloads of the pretty spotted-leaved Lungwort (*Pulmonaria officinalis*), and all these are seldom or never seen, except by the gamekeeper or woodman. Numbers of our native flowers are very beautiful, and there can certainly be no harm in removing them from a private copse to adorn and beautify a private drive.—D. UPHILL, Moreton, Dorchester.

NEW CLEMATISES.

GREAT numbers of new varieties of these beautiful spring and summer-blooming climbers are now attracting attention, and some account of them can hardly fail to prove of service to those who are on the look-out for new plants characterised by real advance in their several properties. All novelties are not necessarily improvements, for some of them actually savour of retrogression, and it is well that those who write for the information of the inexperienced should be able to indicate the new introductions that it is most desirable to cultivate. We have now a wealth of these beautiful hardy climbers, and it is of importance that what is recommended as new should not be mere repetitions of what has gone before. The varieties of the Clematis are now multiplied with great rapidity, and there is a danger that the difference in each variety may not be sufficiently marked as to constitute a distinct form. *C. ascotensis* is one of the newer types, and is a seedling raised by the late Mr. John Standish. It is of a fine pale blue colour, rather brighter than *C. tunbridgensis* (a fine variety, that is not nearly so much grown as it deserves to be). The flowers are large, stout, and of fine form. Beauty of Surrey, one of Messrs. Jackman & Son's new varieties, partakes of the character of *C. lanuginosa*, the flowers very large, and of a charming light greyish-blue colour, and it is considered a decided advance towards a bright blue summer Clematis. I am of opinion that we already possess this in *Lady Bovill*, a very free-flowering variety of a pleasing pale blue colour. *Excelsior* (Cripps & Son) is a rich deep mauve-coloured variety, with a tendency on the part of the flowers to grow semi-double; it is this characteristic which gives it a value, and I mention it accordingly. I fear, however, it is likely to prove disappointing to many. *Fair Rosamond* (Jackman) is a grand variety of the patens or spring-blooming group, with large flowers of a blush-white tint, with an indistinct wine-red bar up the centre of each sepal. This variety is reported to be highly fragrant, which is an additional recommendation; but it should be stated the fragrance is much more perceptible under glass. *C. John Murray* (Jackman) belongs also to the patens type, and it is alike free-blooming and free-growing. The flowers are of a deep purplish-mauve, becoming reddish towards the base of the bar. Mr. Jackman regards this variety as being somewhat intermediate in season between the spring and summer varieties, and so filling up a kind of pause in the continuity of the floral service. *C. Lady Stratford de Redcliffe* (Jackman) is one of the Jackman section, blooming through the summer and autumn, with large flowers of a delicate mauve, having a greenish tint in the centre bar or rib; this gives a charming light variety among the wealth of deeper-coloured flowers that are now getting so numerous. *C. Madame Van Houtte*, a Continental variety, is one of the *lanuginosa* type, and has large white flowers, suffused with a faint blue tint; the blossoms stout, and of fine form. *C. Marie Lefebvre* is from the same source and of the same character, the colour delicate or pale silvery-mauve, with a bar of a deeper tint. We have now a goodly number of the *lanuginosa* type with pale flowers, and some caution is necessary in insisting on their distinctness of character. *Mrs. Quilter* (Standish) is a large pure white variety in the way of *lanuginosa nivea*, to which section it belongs, but has stout flat flowers, and will prove very acceptable to those who are fond of purity of colour. Among the pale-flowered Clematises, *C. Mrs. Melville*, *C. Mrs. G. Mitchell Innes*, and *C. Thomas Tennant*, are new Scotch varieties of the *lanuginosa* type, raised by Mr. J. Anderson Henry. The former has pale mauve flowers of great size;

Wild Gardens and Woodland Flowers.—When "Exmouth" (see p. 407) speaks of three cartloads of Daffodils covering as many decent-sized copses, he can surely have but little idea of the way in

the second is a double variety, resembling *C. John Gould Veitch* in size and doubleness of the flower, but is of a slightly paler shade of lilac-mauve. It is considered to be much superior to that variety, in that it is a perpetual bloomer, commencing in early summer, and continuing to flower till late in the autumn; of a delicate pink colour, changing to ivory-white with age. This produces enormous flowers, in fact, the prevailing characteristic of all the varieties of Mr. J. A. Henry's raising is the enormous size of their flowers. It is recommended by those who are sending it out as the finest light-coloured Clematis in cultivation. *C. Stella* (Jackman) is one of the patens type, with light violet flowers, and a distinct bar of deep reddish-plum colour in the centre of each sepal. This is a delicately scented variety, and it is pleasant to find Mr. Jackman's endeavour to impart fragrance to his new varieties attended with so much success. The Queen (Jackman) comes into the same spring-flowering division, with large finely formed flowers of a delicate lavender tint, scented with the perfume of the Primrose. Lastly comes *C. Victoria*, one of the *C. Jackmani* section, and producing deep reddish-mauve flowers of a very distinct hue of colour.

Were the new varieties raised during the last seven or eight years calculated, and their total given, the number would be astonishingly large, but large as it is, there is scarcely an inferior one among them. A greater reason for wonder is that these fine hardy Clematises are not more grown, for they stand unrivalled for their effectiveness and adaptability for all purposes of garden and conservatory decoration, and, seeing how much hardihood of character they possess, they ought to be as generally grown as the Virginian Creeper and Woodbine. What a fine feature they would make on roadside villas and cottages! Their hardihood—at least that of the varieties of the *C. Jackmani* type—has been placed beyond doubt, thereby eminently fitting them for shady and effective growth in such places. The varieties of *C. patens* and *C. lanuginosa* are decidedly of a more tender character, and this should be borne in mind when a selection of position for their growth is being made. The better the plants are established, however, the more likely are they to pass through the ordeal of severe weather with comparative safety. QUO.

BEDDING PELARGONIUMS TRIED AT CHISWICK.

AN extensive collection of these was arranged for comparison in the trial beds last year. Out of 350 varieties the following received first-class certificates:—

I.—Scarlets.

1. **Harry King** (E. G. Henderson & Son).—A showy variety of moderately vigorous habit, with zonate leaves; the flowers are of good shape, freely produced in moderate-sized trusses of a bright scarlet with a white eye.

2. **Rosa Little** (H. Little).—A dwarf-habited variety, the leaves having a vandyked zone; the flowers, of which both pip and truss are large and fine, are of a rich deep solid scarlet colour, with a small white eye. The flowers are well displayed and of exquisite shape.

3. **Tyrnal Rival** (Laing).—A dwarf, compact-growing variety, the leaves of which are marked with a dark zone; the flowers are large, of fine form, and produced in tolerably full trusses, the colour being a rich scarlet with small white eye. It is a fine zonal scarlet.

4. **General Outram**.—A variety of a medium vigour and of a spreading habit of growth. The leaves are dark-zoned, and the flowers, which are borne in large bold trusses, are of a rich deep scarlet, the individual pips being of free shape and quality.

2.—Rosy Crimson or Cerises.

5. **Caxton** (Pearson).—A variety of moderately dense habit and of even growth. The leaves are green without zones. The flowers are moderate-sized, in rather small but dense trusses, and are of an intense rosy crimson, and very effective.

6. **Colonel Wright** (Pearson).—A fine, close-habited, and very showy variety, of medium vigour of growth. The leaves are green, not zoned. The flowers, which are freely produced in large trusses, are of a light rosy scarlet, and very showy. The flower trusses are abundant, and hence very effective, as well as from being whole-coloured, which gives them a density and solidity which is absent from shaded flowers.

7. **Mark Twain** (F. Miles).—A dwarf-growing variety of spreading but compact habit, and a free bloomer. The leaves have a dark zone, and the flowers are large, in large trusses, and of a deep opaque scarlet. The individual pips are fine, and hence the variety is an effective one.

8. **Mrs. J. George** (W. Paul).—A variety of dwarf and moderately vigorous habit. The leaves have a broad faint zone. The flowers are produced in remarkably fine trusses, and are individually of good size and possess form as well as quality, the colour being a pale scarlet.

3.—Pinks.

9. **Lady Emily** (Pearson).—A dwarf-growing vigorous variety of spreading habit, with pale green leaves. The flowers are of a bright deep pink, white at the base of the upper petals, the pips being large, and the trusses fine.

10. **Lucy** (Pearson).—A variety of tolerably compact habit and a free bloomer. The flowers are of a fine rose pink and are borne in medium-sized trusses.

11. **Mrs. Augusta Miles** (Pearson).—A compact-growing variety of moderate vigour, with green leaves of medium size. The flowers are borne profusely in trusses of moderate size of a deep bright pink with white eye, which makes them very attractive.

12. **Mrs. Holden** (Pearson).—A variety of compact, even growth, producing its medium-sized trusses of blossom in profusion. The flowers are of a bright pink colour and remarkably showy.

4.—Bronze Zonals.

13. **Rev. C. P. Peach** (Laing).—A showy variety of dense, compact, even growth, with large leaves of a greenish-yellow colour, marked by a broad, deep, copper-coloured zone. Flowers light scarlet.

14. **W. E. Gumbleton** (Laing).—A variety of compact growth. The leaves greenish-yellow, with a broad zone of a dark bronze colour and a narrow yellow-green border. Flowers scarlet.

5.—Gold-leaved.

15. **Golden Harry Hieover** (E. G. Henderson & Son).—A variety of dwarf, spreading, free-growing habit. The leaves are golden green, with a narrow vandyked zone of dark bronze and broad golden edge, very showy. Flowers scarlet. A very desirable variety.

6.—Ivy-leaved.

16. **Gem of the Season** (S. Ford).—A variety of free rambling growth, with green Ivy-like leaves, and abundant flowers of large size and a pale rosy-pink colour. The flowers are very freely produced, but do not stand well; it will nevertheless be useful for baskets.

17. **Argus** (G. Smith).—A variety of moderately free growth, with green Ivy-like leaves slightly marked with brown. The flowers are of a deep rosy-pink, with dark spots on the upper petals, and are of a tolerably good shape.

It is proposed amongst the other trials of 1876 to grow all the Ivy-leaved varieties obtainable, and which are now rather numerous, as pot plants, since they are an extremely interesting group, and are more useful under glass than in the flower borders. T. MOORE.

PROPAGATION AND CULTURE OF VERBENAS.

VERBENAS, as decorative plants for flower garden purposes, seem to have fallen back of late years, an occurrence to be regretted, inasmuch as we possess no other plants in all respects calculated to fill their places. Verbenas, it is true, sometimes die suddenly in large patches during the height of the flowering season, but this fault, I think, might be overcome by paying a little more attention to the wants of the plants. It is well understood that if it be desired to prevent degeneracy in any family of plants, change of both soil and locality is necessary. Nevertheless, in defiance of this we propagate year after year from the same stocks for the purpose of replenishing probably the same beds, quite overlooking the fact that the principal elements in the soil required by this particular plant may be exhausted from being repeatedly cropped with Verbenas. It is generally admitted that if we wish a good crop of Potatoes we must get seed-tubers from a different locality from that in which they are to grow; and the greater the difference existing in the soils the better will be the result. These principles are, I fear, too often violated with respect to Verbenas, and the same thing happens in the case of the Calceolaria, and, perhaps, with the exception of the Pelargonium, most plants will ultimately undergo a similar physical degeneracy if this matter be disregarded. The remedy is, therefore,

in our power, namely, exchanging cuttings one with another from distant places, and changing the soil in the beds.

Propagation by Seed.

To succeed in flowering seedlings the summer following the sowing of the seed, it is best to sow in September, early in the month, and to keep them steadily growing throughout the winter. When the seed is sown, plunge the pots in a frame where the temperature is kept about 60° at night; keep the soil damp, but not sodden, and to prevent much watering being required, cover each pot with a bit of glass until the seeds vegetate and break the surface. Prick out the plants into single pots when they have formed a couple of rough leaves, and place them near the glass all the winter, being rather sparing in the amount of water supplied them until there is more sunshine and longer days. A second shift may be given them at the latter end of April, which will add much to their vigour before being planted out into the testing-ground out-of-doors; but should the plants be wanted to flower inside, they should have a third shift into 5-in. pots before flowering.

Propagation by Cuttings.

When speaking of any plant that roots easily, the common expression used is that it will "strike like a Verbena," a circumstance which explains how easily Verbenas are multiplied in this way. For spring practice the best plan is to take a number of 9-in. saucers, and fill these with silver sand in a loose manner; then put as much water into the saucers as they will contain, thereby making the sand look in consistency like pulp; the cuttings should then be inserted as thickly together as possible; each saucer should then be placed inside a similar sized one, filled and kept full of water; these should be put in a hot place, such as on a flue or pipe in a Vinery or other house. They should then be placed in the sunshine, and the moisture maintained by keeping the outermost saucer filled with water, none being put on the cuttings from that they are inserted until they are rooted. In this way we have rooted thousands with but a nominal percentage of loss. The cuttings root sufficiently for potting off in the course of eight or ten days, and the smallest cutting succeeds. With reference to potting when struck, a thin flat piece of stick is used for the purpose of removing them in a body from these saucers; and the sand breaks up readily, while the young plants separate with a good ball of sand adhering to their roots. Fill a number of 3-in. pots loosely with rich light compost, insert the fore-finger into the centre of each pot, and then drop a plant with the ball entire into each, adjusting the compost moderately firm round the roots. Water well, and re-plant in heat; shade for the first few days if the sun shine brightly, otherwise shading is not required. When these plants have established themselves in their pots, they may be put in a cold frame to harden off prior to being planted out.

Pot Culture.

Verbenas are often used for the adornment of the greenhouse and conservatory, and beautiful objects they are when well grown; but to accomplish this in the case of Verbenas, as in that of every other plant used for a similar purpose, they must be attended to constantly and well, never allowing green fly or mildew a footing on them, nor the shoots to fall over each other by getting top-heavy through neglect of supports or the want of pinching; do not over-pot with the object of saving time. The rule to follow in regard to potting is to give larger shifts whenever the pots get filled with roots until the plants have reached the dimensions desired, pinching out the points of those shoots that threaten to destroy the symmetry of the plants through too vigorous growth. The compost should consist of three parts light fibry loam, one part leaf-mould, and one part fresh horse-droppings rubbed through a sieve; the loam should not be sifted but well broken up, and these three ingredients should be properly incorporated. Drainage is an important consideration; let this be open and free by placing carefully plenty of broken pots into each pot, and covering these with a layer of fibry turf or Moss. Water copiously from the time when active growth commences until the flowering is over, they should also be syringed in sunny days with soapy water twice a week to prevent green fly or mildew becoming established. Ventilate freely when the air is mild and dry, but be careful of this in foggy weather.

Select Bedding Verbenas.

Crimson King must be regarded as the best bedding kind in the crimson division; it is dwarf, vigorous, and of uniform growth, affording a blaze of bloom dense and brilliant. Snowflake holds its place as a good white, but it requires slightly more pegging down to prevent its rambling. Purple King, the most popular of Verbenas, is dwarf and compact in habit, and a profuse flowerer. Lord Raglan is next to Purple King as regards hardness, and it is a superior

flower both in pip and truss; colour, magenta scarlet. Old Scarlet Deliance is unsurpassed both as regards growth and blossom; it still retains its hardy vigorous properties, and is as serviceable as when we first knew it, although it has outlived scores of rivals. Géant des Batailles, another most vigorous spreading kind, with large lurid-crimson flowers, stamped with maroon around the eye, is an old and well-known sort. Firefly, a dazzling scarlet, has a neat truss. Leah is a soft pink kind, with a crimson eye. La Grande Boule de Neige is a beautiful white sort. Ladybird, flesh colour, has a purple stain around the eye. Jupiter is rich plum, but on the whole, although there are plenty of pretty varieties of this rich, dark plum shade, none of them keep their richness against sun and rain. Rev. S. L. Hole, pale lilac, tinted with crimson, has a splendid truss, and is a most profuse bloomer.

Varieties best suitable for Pot Culture.

Apollo, blush, has an immense truss of extra large flowers; King of Lilacs, lavender blue, is another splendid sort; Géant des Batailles; Foxhunter, scarlet, with white eye; Rev. S. R. Hole; Rev. P. M. Smith; Princess of Wales, a delicate pink and white striped variety; Prince of Wales, a splendid scarlet self; Richard Dean, a purple kind, with a bold white eye; Thomas Harris, mulberry, with clear white centre; Enchantress, white ground, stamped with purple over the centre; and Carnation, white and crimson striped, are all good kinds.—"The Gardener."

Selecting Plants for Spring Gardens.—It is a mistake, and a very common one, to use plants for spring gardens that do not attain their full beauty until the beds are required for their summer occupants. We are constantly hearing complaints of the shortness of the summer display, and yet by having beds filled with late-blooming spring plants the season is still further reduced, owing to a reluctance to remove plants in bloom to make room for their successors. Beautiful as Collinsias and many other plants are that flower in May, they are better adapted for the decoration of mixed borders than for flower-beds; and, if Calceolarias and similar plants be not planted out before the end of May or beginning of June, a successful result need not be looked for.—J. Groom, *Henham*.

Yellow Wallflowers.—The tall golden-yellow variety, mis-named Tom Thumb, is a fine kind for spring decoration, producing just now a splendid mass of colour. It is a robust grower, and has flowers of fine form and substance, rivaling in size the best of the crimson kind. It is an excellent kind for furnishing out flowers, as its trusses are borne on long straight stalks. As a rule, the yellow is truer to character than the crimson, as many of the latter are apt to run into lighter hues, whilst the true yellow never varies. If some enterprising flower-grower for market would try this variety for one season, I do not think he would have cause to regret having done so. The old Belvoir Yellow has the most compact habit for bedding purposes, but of late it has to some extent lost its character for constancy, and does not now come so true from seed as formerly.—D.

The Utah Aloe (*A. Utahense*).—This is a new species recently described by Englemann, and collected by Dr. Palmer and Mr. J. E. Johnson. It is well worth the attention of horticulturists. The leaves, which are as usual thick and fleshy, terminate in a strong spine, the margins mostly spine-toothed, 1 ft. to 2 ft. long, a crowded crown ranging from the base of the flower-stem, which is only 5 ft. or 6 ft. high, springing from a short stump or trunk. The flowers are small and yellow, close set against the main stem in pairs or fours.—Dr. Kellogg. [This is probably a hardy species.]

Perennial Larkspurs.—Great improvements have, according to the "Florist," been worked among Delphiniums during the past few years. A bed of them finely flowered is a striking object in its rich hues of blue. The double and single forms alike have been subject to the change, and the long, huge, symmetrical, closely-set spikes are objects of great beauty. Among the double flowers the following are particularly fine:—Argus, azure-blue striped and tipped with rose; Clare Courant, bright azure-blue, distinct and very fine; grandiflorum plenum, rich dark shining blue, tinted with bronzy red, large full flowers; Herman Stenger, outer petals bright violet-blue, centre petals rosy pink, very fine; Keteleeri, a distinct and beautiful variety, producing freely dense spikes of lavender-blue flowers; Paul et Virginie, outer petals bright blue, centre petals bronzy red, striped and edged with white, very showy and striking; Roi Leopold, outer petals bright blue, inner petals rosy violet, centre sulphur and white, very fine; and Thiers, azure-blue, centre white and rosy pink, very distinct and beautiful. Of the single flowers, which, after all, are the most striking, the following are effective:—amabilis, azure-blue, changing to rosy lilac, white and orange centre, a very distinct effective and very beautiful variety; Celestial, ultramarine-blue with

conspicuous velvety brown centre, very effective and striking; formosum lilacinum, light lavender, tipped with pink, ornamented white centre, very distinct and extra fine; La Belle Alliance, bright violet-blue, with a white and orange centre, very beautiful; Madame Henri Jacotot, bright azure-blue, suffused with delicate rosy pink; nudicaule, bright orange-red, dwarf, very distinct and effective; and pulcherrima, rich shining blue, changing to reddish bronze, orange and white centre, a very distinct, effective, and beautiful variety.

THE CASTOR-OIL PLANT AS A TREE.

IN France, under favourable circumstances, Castor-oil Plants

sometimes grow to the height of 10 ft. or even 12 ft., and have leaves nearly a yard in width. In this country they give indications of becoming arborescent in autumn; but the cold weather which soon afterwards sets in puts a stop to further progress in that direction. The Tree Ricinus is not a distinct species; on the contrary, it is the type of all the varieties with which we are acquainted, and may be met with continually in warm climates, like those of the Riviera and Algeria, and even as far north as Montpellier, provided it be protected against frost by straw or matting. The common Castor-oil Plant likes a warm aspect and a light rich soil. It is easily, as all of us know, raised from seed, which should be sown in heat early in spring. As soon as the young plants are old enough to handle, they should be pricked out separately into pots, and again placed in heat. They must be well watered and shaded until they have become thoroughly established, and should be allowed plenty of air on fine days, otherwise they will throw out long, weak shoots that very materially detract from their beauty. Their growth being very fast, the roots soon fill the pots in which they have been placed, and when that occurs they must be shifted into larger ones. Towards the end of this month they may be gradually hardened off, and finally transplanted out-of-doors in good rich soil, when all danger from frost is over, care being taken to give them plenty of

water in dry weather. When Castor-oil Plants are once transplanted, their roots spread so rapidly that they cannot be lifted and potted again successfully; therefore, if they are to be grown in pots they must always be kept potted, shifting them, of course, into larger ones from time to time. The only care which they require during the winter is frequent but moderate watering, giving them air whenever the weather is favourable. Thus treated Castor-oil Plants may be kept in growth and beauty for several years in succession, when they will form trees, which, if not as large as that here represented, or those grown in more favoured climates, will at least add beauty to our gardens in summer. The most notable varieties are Ricinus sanguineus, the stem, leaf-stalks, young leaves, and fruit of which are of a blood-red colour; R. borboniensis, which in southern climates attains a great height; and R. giganteus. Q.

The Castor-oil Plant as a Tree.

The Rocky Mountain Columbine (*Aquilegia cœrulea*).—Having gathered some hundreds of blossoms of this beautiful Columbine in its native country, *i. e.*, the eastern slope of the Rocky Mountains, will you allow me to differ from some of the conclusions in the admirable article on Columbines in *THE GARDEN* of April 22. Mr. Niven divides *A. leptoceras* of Nuttall into two distinct varieties; this, I venture to think, is unnecessary, as in almost every case I have found plants bearing blue flowers growing side by side with those bearing yellow and pinkish flowers, and every intermediate shade between the two extremes well represented. This leads me to adhere to Professor Porter's description of this Columbine, and to the best known name of *A. cœrulea*, in the "Flora of Colorado," and to Professor J. N. Coulter, in his botanical paper in the "United States Geological Survey Report on Montana in 1872."—"Flowers 2 in. to 2½ in. in diameter, pale blue; sometimes ochroleucous, pinkish or white." In my experience the blue flowers fully equal the yellow in size. The finest patch I ever found was on the edge of the great Pine forest that covers the slopes of Pike's Peak, Colorado. The flowers were nearly all blue, of an immense size, and shone out from under the shade of the *Pinus ponderosa* like pale blue stars. This plant flourishes on shaded mountain slopes in alluvial soil from 7000 ft. to 11,000 ft. altitude, throughout the territories of Colorado, Montana, Idaho, and Wyoming.—ROSE G. KINGSLEY, *Byfleet*.

Chrysanthemums as Bedding Plants.—Independently of their value for conservatory decoration in pots, the following four sorts of Chrysanthemums make first-rate summer and autumn bedding plants. They are neat and dwarf in habit, and profuse and continuous bloomers, admirably adapted for back lines in wide borders, or for masses in large beds. They are not, we think (says the "Gardener") so well adapted for cold late localities as for early ones, still they are worth trying experimentally even in the coldest places, for the sake of variety. They are capital plants for the conservatory when planted in the open ground and lifted and potted after the flowers are formed. The sorts alluded to are *Delpheine Caboché*, a

kind which grows about 2 ft. high, and which is neat and compact in habit. The flowers are of the Pomponne class, very double, and of a fine rosy-purple colour. It blooms profusely, when planted out, from July to October and November, and where the climate is favourable, it continues on to Christmas; in wet cold places it cannot be expected to last so long. The next is called *Illustration*, a variety not so tall as the preceding, being about 18 in. high. Its flowers are very double and excellent in form, but small—light pink on the margin, shading into clear orange in the centre. It blooms along with the preceding, and to the same late period, in great profusion. The third variety is *nanum*, a sort which grows to about the height of the last, but which has flowers about twice the size; they are white changing to rosy-lilac. It comes into bloom rather earlier than the other two, but lasts quite as late. *Precoité*, the fourth kind

referred to, grows to the same height as the two last. Its flowers are medium-sized, bright golden-yellow, and are produced in great abundance from July to December.

Protecting Choice Hardy Plants from Slugs.—Many hardy flowers of the choicest and newest kinds perish from the attacks of slugs, sometimes without the cause being observed. To the climate, or the soil, or to the fact that the lost favourite is "Alpine" in its character, is commonly set down the damage done by slugs, which are nowhere more abundant than on many rock gardens, where the rarest flowers are set. Among the various ways of saving plants from these enemies, we have seen nothing more effectual than the perforated zinc protectors, first described in THE GARDEN by the Rev. Mr. Ewbank. A strip of perforated zinc, 4 in. or 5 in. high, is placed round the plant overlapping a little at the junction, and this acts as a complete protector. There is good evidence of its value to be seen in Mr. G. F. Wilson's garden at Weybridge Heath, where many of the plants are thus protected, and in consequence quite uninjured. This perforated zinc is to be obtained from Messrs. Beaby & Co., Fitzroy Works, Euston Road.—V.

Wild Gardens and Woodland Flowers.—I venture to say that had "Exmouth" been better acquainted with the particulars of the case to which he refers (see p. 407), he would not have written as he did. The fact is, the three cartloads of Daffodils were not "stolen from meadows, banks, hedges, or copses," but were dug out of an old orchard, about one-third of the surface of which was covered with Daffodils. The occupier of the orchard asked me to take as many away as I wanted; I therefore thinned out two cartloads, leaving in the ground probably three cartloads more; but the tenant, thinking that I had not taken as many as he would like to get rid of, dug up another cartload and sent them to me. Your correspondent should remember that the Daffodil is considered to be a poisonous plant, and is of no use as herbage; therefore, a tenant who has to pay a high rent for Grass land looks upon Daffodils when growing in such masses as mere weeds. Allow me also to inform "Exmouth" that they were not planted "alongside a drive where but few can delight in seeing them." On the contrary, the drive in question, where the three cartloads were planted, is as free and open to the public as Hyde Park; it is indeed the most frequented drive on the estate, being used by thousands from villages and towns far and near. Lastly, the two cartloads of Lily-of-the-Valley were planted near the same drive, and were brought from an outlying copse where acres are overrun with this plant, and where the public are not allowed to enter. After this explanation I leave your readers to judge whether or not I deserve the harsh remarks applied to me by "Exmouth."—A. FORESTER.

Hedges and the Wild Garden.—The writer planted a hedge entirely of Wild Roses, a few years ago, and sowed the berries of the Briony and the Traveller's Joy or Wild Clematis between the suckers of Wild Roses; everything grew with astonishing rapidity, and in about four years the hedge was invulnerable. No bushes of any kind had been introduced, and consequently, although the hedge was a mass of blossom, and beautiful both from flowers in the summer, and berries in the autumn, it naturally became top-heavy from the want of support, and tumbled down after reaching the height of 4 or 5 ft. But had a very few trees or bushes been planted at the commencement—say a yard or more apart—the Roses would have had sufficient support for their long thorny branches to have rendered the hedge firm as well as invulnerable and beautiful. The Traveller's Joy is a most useful as well as ornamental material for hedges; the strength of its interlacing branches is extraordinary, and will form a resistance equal to small ropes, whilst the thorns of the Roses defy the intrusion of hands or feet.—L. L.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

The Official Rhubarb.—I can testify with "Oron" as to the remarkable vigour and fine effect of Rheum officinale, which is likely to be very valuable for the wild garden. I notice in my collection that Rheum Emodi is only now pushing its first small leaves above ground, whereas the Official Rhubarb appears to be at full growth so far as its leaves are concerned. Doubtless, it may also have some culinary value.—V.

Camellias Out-of-doors.—A correspondent having made some remarks upon out-door Camellias as being very rare, it may be interesting to him to know that I possess a tree of the Red Camellia, growing against the wall of a hothouse, which is more than thirty years old, and which never fails to produce hundreds of blossoms commencing in the month of February; last year it had considerably more than a thousand. I have another White Camellia growing against the wall of a pit which blossoms freely annually, and I have others against a wire trellis without any shelter at the back which likewise blossom well.—Y.

Pelargoniums grown on Turves.—Mr. Webber has called our ("Gardener's Chronicle") attention to an admirable plan of growing bedding Pelargoniums on turves instead of in pots. It seems that the cuttings are put into 48-pots in the ordinary way in September, and stored in such pots until the month of March, when they are planted on or in the turves, and make fine plants by bedding-out time.

ROSE LORE.

MANY persons who have taken so prominent a part in public life as to have attracted the attention of history share, according to the "Pall Mall Gazette," with the black-beetle a positive distaste for the Rose. The famous Chevalier de Guise could not smell a Rose without feeling uncomfortable; and Venieri, one of the Doges of Venice, suffered under the same disqualification for the pursuits of gardening. Anne of Austria, wife of Louis XIII., could not even look at a Rose in a painting without being seized with tantrums. Nevertheless, many people who are willing as a rule to take examples from the great have persisted in entertaining friendly sentiments towards this flower, and every time that the spring and early summer bring back the pretty vegetable they fall to telling one another all they know about it. In the East there is still a belief that the first Rose was formed by a tear of the prophet Mahomet, but nations of more cool and disciplined imagination have sometimes admitted that its origin is lost in obscurity. Roses were used very early in history among the most potent ingredients of love philters. They seem to have been imported by the Romans from Egypt until the reign of Domitian. Antiochus slept upon a bed of Rose-leaves. Mark Antony begged that Cleopatra would cover his tomb with these flowers, and "mea rosa" was a favourite term of endearment among Roman lovers, as one would say "mon chou" (my Cabbage) nowadays in France. Homer has adorned the shield of Achilles and the helmet of Hector with Roses. Among the Greeks it was the custom to leave requests for the maintenance of sepulchral Rose-gardens over the grave of the testator; and at Torcello, near Venice, an inscription may still be seen that shows that this fashion was adopted in Italy. In Stock's collection of engravings on stone there is a beautiful design cut in garnet. It represents a butterfly settling on a Rose, and it is supposed to commemorate the death of a young girl. In Turkey a stone Rose is often sculptured above the graves of unmarried women. A charming bas-relief on the tomb of Madame De la Live, who died at the age of twenty, represents Time moving a Rose with his scythe. According to Indian mythology, Pagodasiri, one of the wives of Vishnu was found in a Rose. Zoroaster is said to have made a Rose-tree spring out of the earth and bid him to perform a miracle. In Babylon a preparation of shoe-leather was much esteemed when it had been impregnated with the scent of Roses; and Abdulkari, an eminent Turk, who wanted to live there, being made aware of this fact, discovered an ingenious way to profit by it. In reply to a demand which he had made for the freedom of the city, the Babylonians sent him a bowl brimful of water, to signify that there was no room among them for an intruder. Abdulkari placed a Rose-leaf on the surface of the water without spilling a drop of it, and having thus indicated that he might be received without making a mess, he obtained the object of his desire.

In one of the books attributed to Solomon eternal wisdom is compared to the plantations of Rose-trees at Jericho. Princess Nourmahal, the most lovely lady in the harem of a Great Mogul, had a canal filled with Rose-water and rowed about on it with her august consort. The heat of the sun disengaged the essential oil from the water, and their Majesties, having observed the fact, invented otto of Roses. The Emperor Heliogabalus filled a fish-pond with Rose-water—it is nowhere said whether the fishes approved of this proceeding. When the Soldan Saladin, who had so much trouble with hard-fisted English King Richard and his turbulent Christian friends, took Jerusalem in 1188, he would not enter the Temple, which he profanely called a mosque, till he had had its walls washed with Rose-water, and Saout assures us that 500 camels were no more than sufficient to carry the purifying liquid. Also, after the taking of Constantinople by Mahomet II. in 1455, the church of St. Sophia was solemnly purified with Rose-water before it was converted into a mosque. The high priest of the Hebrews wore a crown of Roses when he offered up certain sacrifices under the Mosaic dispensation; and it was perhaps in remembrance of this fact that the Synod of Nismes, which was held in the third century, enjoined every Jew to wear a Rose on his breast as a distinguishing mark of inferiority. In many countries the Jews still celebrate the festival of Easter Flowers, during which they ornament their lamps, chandeliers, and beds with Roses. Thus it happened that these flowers were hateful to the early Christians, and are often condemned in the writings of the Fathers, who professed that they could not understand that pious people could think with equanimity of Roses when they remembered the crown of thorns; afterwards this hostile feeling seems to have died out. When Marie Antoinette passed through Nancy on her way to be married to Louis XVI., the ladies of Lorraine prepared her a bed strewn with Roses. In the Middle Ages Roses were held so precious in France that a royal licence was necessary to grow them. Charlemagne recommended the cultivation of the Rose in his "Capitulation." The Persians of Shiraz stop their wine-bottles with Roses,

which give the wine a pleasing smell; and during the festival of Abrizan, which takes place during the equinox, Persian ladies throw Roses at each other when they pay visits. At Rome it was the practice of the Church to bless the Rose on a special day set apart, which was called Rose Sunday. The custom of blessing the Golden Rose seems to have begun in the eleventh or twelfth century. The benediction was pronounced with particular solemnity on the fourth Sunday in Lent, and the Golden Rose thus consecrated was given as a mark of the Sovereign Pontiff's favour to some prince or princess. Alexander III., who had been received with great honour during a journey which he made in France, sent the Golden Rose to Louis the Young as a sort of graceful compliment. Subsequently the giving of the Golden Rose became an authoritative act by which the Pope officially recognised the rights of Christian sovereigns. Thus Urban V. gave the Golden Rose to Joan, Queen of Sicily, in 1368, thereby preferring her to the King of Cyprus. Henry VIII. of England received a Golden Rose both from Julius II. and from Leo X. Towards the close of the last century the Golden Rose appears to have been given almost indiscriminately to any travelling prince who would pay a sum equivalent to about £400 in fees for it.

There are an infinite variety of stories about Roses. When Milton was blind the Duke of Buckingham, who visited him, observed that his wife was a Rose. The lady had a fine high temper, and so Milton answered that doubtless she was, for he could feel her thorns. Frederick the Great was walking in the gardens of Potsdam with Voltaire, and asked the amazing Frenchman for a Rose. He picked one, and presented it to the king with the remark that it had grown beneath his Majesty's laurels. Luther had a Rose given on his seal. A Rose-tree in the park of Roxburgh marks the place where James II. of Scotland died. At Santiago, in Chili, whenever a stranger is received in a house, each of the ladies of the family offers him a Rose. To show the preference which Madame de Genlis entertained for old men above old women, she was fond of saying that Oaks improved with time, but Roses faded. It may be mentioned in passing that Madame de Genlis has the credit, if we have been rightly informed, of having introduced the first Moss Roses ever seen into France.

Among the incredible number of names given to Roses there is the Rose of Scotland (R. spinosissima); it is a very prickly flower. The Rose of York and Lancaster (Rosa damascena var. colorata), a red and white Rose, recalls the ending of the greatest English civil war. There is quite a nobility of Roses, nearly all the heroes and heroines of history being identified with some flower of this type. It is as good a nobility as any other. There is even a Brown Rose (R. Brownii) in Nepal, which will transmit that gentleman's name to posterity with the Lawrence Rose; but the Brown Rose will not survive a frost, says the perfect gardener. Among the Greeks, the Romans, and the Gauls, Parsley, Ivy, Myrtle, and Roses were looked upon as valuable remedies for people who had drunk more wine than was good for them. In Capua Roses were employed by the local medical men as tonics good for stomachs fatigued by over-eating. A decoction of Roses was supposed to have excellent astringent properties. Hoffman recommends it in pleurisy; Paracelsus thinks that when mixed with honey it will lengthen life. A long list of authorities may be produced to show that Rose-leaves discreetly used are a perfect cure for hydrophobia. A spirit made or flavoured with Roses was the favourite cordial of Philip the Handsome, and was considered by Charlemagne as a specific against fainting from loss of blood in battle. A poultice of Roses was long employed for flesh wounds, and Roses preserved are still believed in many places to cure consumption and all diseases of the throat and lungs, a welcome statement, if supported by fact; but that is not the case. The best preparation of them is said to be made from Rosebuds and sugar in equal parts.

The Albert Memorial in Hyde Park.—The history of this, which is certainly no addition to the charms of Hyde Park, is traced in the April number of "All the Year Round." According to it, "Decorative Art" demanded that the bronze statue should be gilt; and the result is the monstrosity now on view in Hyde Park. Description fails to convey any idea of the frightful reality. There is an old Greek story of a banquet from which the sun turned away his eyes; but the pale luminary which visits London appears to take delight in dwelling on the gilded effigy—in playing round it, and in revealing its barbarous ugliness. With the gold scraped off, the statue would be—no far as a sitting statue can be—well enough; but the glittering surface sets all artistic effect at naught. And this is the outcome of £120,000—a gingerbread spire of faded gold, and a glaring colossus, the laughter of foreigners and the wonder of nursemaids.

THE GARDEN IN THE HOUSE.

VASE OF SIMPLE FLOWERS.

At the present moment I have before me a little floral table ornament, consisting of very simple flowers only; and yet this arrangement has such a pretty effect that I am tempted to give a description of it. The stand or vase is as simple as the flowers which it contains, being of wicker-work varnished, so as to give it a light brown colour. Its form is that of a flat tazza, containing a zinc pan about the size of an ordinary saucer, perhaps a little larger. Out of this rise three rods about 12 in. long, drawn together in the form of a tripod, and which support another tazza of a much smaller size than the lower one. Resting on the ornamental basket-work round the edge of the lower tazza are placed small fronds of hardy Ferns and leaves of the Lily of the Valley; the tazza itself is filled with blue Wild Hyacinths and Lily of the Valley, with some of the leaves of the latter, and a few fronds interspersed. Up the rods which support the upper tazza are twined sprays of small-leaved Ivy, the young shoots and leaves of which at this season have so many pretty tints. The upper tazza is dressed similarly to the lower one, with the exception of the introduction of a few young spikes of Ribbon Grass, which give a graceful finish to the top. This little arrangement is not suited for being subjected to artificial light, as the blue of the Hyacinths loses its pretty shade; but for the decoration of the drawing-room this is not of so much importance as if it were required for the dinner table. Last week this same vase was fitted up with Lily of the Valley and pink China Rose-buds, which looked very well, but the China Roses soon drop their petals; therefore, arrangements in which they are introduced do not last long in a fresh state compared with other flowers. The stools of Ribbon Grass will be found at this season to be very useful for decorative purposes; while young they have many pretty shades, and have not the heavy look which they acquire later in the season.

A. HASSARD.

Cut Flowers: How to Preserve them.—For this purpose nothing is better than rain-water, which should be changed every day, or every alternate day. Before arranging the flowers in the glass or flower-stand, trim the ends of the stalks with a sharp knife, so as to make a clean cut. The stems are often bruised in the plucking; the bruised part decays, and renders the water sooner impure and unwholesome than would be the case were the water absorbed through a clean-cut section of the stem, which will perform its functions without decay till the flowers have faded. To guard against the possibility of any unpleasant smell, and for other reasons—seeing that water is an absorbent of noxious gases—if the flowers be intended for a close sick chamber, let the water be changed every day; by this means any unpleasant smell will be avoided. Camphor has been suggested as a sort of disinfectant, and at the same time as a material likely to prolong the beauty of the flowers. Its advantage is, however, more imaginary than real; therefore do not trust to it as a substitute for the small amount of trouble incurred in the simple process above suggested. Salt has also been used; but though it may not hurt some flowers, there are others which will be injured by it. In flower-stands where sand is used, and must necessarily remain for some time, mix with the sand one-eighth part in bulk of small pieces of charcoal, broken about the size of Peas; this will keep it sweet for weeks. The above advice is given by Mr. Niven, of the Hull Botanic Gardens, in a small pamphlet descriptive of a successful attempt to distribute cut flowers, &c., among the sick and poor of Hull. It contains hints useful to those interested in organising effectively work of this kind, and is published by W. Harvati, 162, Whitefriargate, Hull.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

The Hart's-tongue Fern as a Room Plant.—In a room in the Swan Inn at Henley-in-Arden, I saw a plant of this on March 17 with more than 100 perfect and large fronds, and with a diameter of nearly 3 ft. I ascertained that it had been in the room for four years, and it was one of the handsomest plants I have ever seen grown in a dwelling-house.—T. RAY.

Pansies Blooming in Water all the Winter.—A lady writes to Mr. Vick January 24: "I must tell you what I've had all the winter.—Pansies! About the 1st of November a friend brought me a bouquet of cut Pansies. I put them in a vase of water, in which they have budded and blossomed all winter. They are now full of buds, and one dear little Pansy, and not so small either, fills my sleeping room with fragrance, so delicate yet so charming."

Daisies for Window Boxes.—Few early-blooming plants equal double Red, Crimson, and White Daisies for outside window-boxes at this season of the year, and when planted in stiff, loamy soil and well watered, they continue to throw up fresh foliage and flowers until even the beginning of June; unlike many other spring-blooming plants, too, they withstand the effects of London smoke. Anemones and Daffodils also make effective window-boxes, but their beauty is short-lived compared with that of the Daisies.—B.

THE KITCHEN GARDEN.

SWEET FENNEL OR FINNOCHIO.

THE Common Fennel (*Foeniculum vulgare*) is a vigorous, perennial, umbelliferous plant, a native of Central and Southern European districts of the Mediterranean regions, and naturalised in England, where it is sometimes found in chalky spots. According to the soil and climate the Common Fennel rises to the height of from 3 ft. to 6 ft., its smooth tubular stem bearing elegantly-cut leaves and yellow flowers in summer. In spite of its very strong odour, however, it has long been cultivated in gardens on account of its leaves being sometimes used in sauce and for garnishing dishes. Oil obtained from the seed is very sweet-scented and well known in perfumery, and the seed itself is largely used by chemists, confectioners, and others; consequently, the cultivation of this plant is carried on extensively in the south of Europe. It is easily propagated by offsets in the spring, by division of the large roots, or by seeds, the latter being by far the best way; but the plant will very quickly spread if allowed to bear seed, therefore it should be treated as a perennial, and the flower-stalks cut down as soon as they appear; the stools must be protected against sharp frost. A variety called Sweet Fennel in England, Finocchio in Italy, deserves a special notice as a vegetable. The habit and colour of the plant are the same as those of the common sort, but the stalks do not attain more than 3 ft. in height, and have a large, dilated, bulb-like growth, just

The Sweet Fennel or Finocchio (*Foeniculum dulce*).

above the ground, which constitutes the edible portion of the plant when blanched, and at every branching point on the stems appear similar fleshy knots but smaller and useless. Between the Finocchio and the Common Fennel several intermediate sorts are cultivated in Italy for the same purpose, but they are all of inferior quality to the true Finocchio. It is such a favourite in the south of Italy, at Naples, and in Sicily, that among both rich and poor it is in daily use on every table; and during the summer a dinner would not be considered complete without the Finocchio. Strange to say, however, in the north of Italy the Sweet Fennel is almost unknown; people not used to that vegetable have a strong dislike to it at the first trial on account of its pungent smell and taste, but after a short time a relish for it is acquired. When the plant is ready for use all the leaves are cut back to the blanched part, and the stool taken up, well washed, cleaned, and divided into four parts; the scales can then be eaten either in their raw state with salt and pepper, with meat alone, in salad, or mixed with salad with oil, salt, vinegar, and pepper like Artichoke, or as a sauce for fish, for flavouring soup, for pickling, &c.; but it is most generally eaten with salt and pepper at dessert. Its cultivation presents no difficulty; a light, rich soil being selected and divided in ridges 1½ ft. wide and ½ ft. deep. The seed is sown in March, in drills 1 in. deep; when once established the young plants are thinned 1 ft. apart, kept free from weeds, and freely watered (irrigated if possible) during dry weather. The plants having attained their full development are earthed up about ½ ft. high; a fortnight after, the base of the stalks will be blanched and become sufficiently tender for use three months after sowing. Subsequent sowings are

made until July to keep up a successional supply all through the summer. To have this vegetable finely flavoured and as tender as possible it must be grown very quickly, consequently it cannot be grown to perfection in the open ground in England on account of the cold and wet climate; it may, however, be sown in a hotted and transplanted under glass until the hot weather set in, when it may be transferred to the open ground with every probability of a successful growth. It is very seldom transplanted in Italy, where it is treated as an annual, though a perennial. The seed retains its vitality for from three to five years, and must be gathered and imported from the Continent.—D. GUIHENEUF.

New Potatoes in Winter.—M. Tellez, a French horticulturist, has practised a method of growing early Potatoes which has attracted a good deal of attention in France. At digging-time sound and medium-sized tubers are chosen and placed in a position in which they can have plenty of cold air so as to retard their sprouting. In August next year they are planted and grown in the ordinary manner, care being taken to cover them thickly with litter as soon as the frost sets in. Grown in this way M. Tellez states that Potatoes may be dug from the beginning of January right up to April or even May, according to the quantity planted. This is known in this country as Chapman's mode of growing Potatoes—a plan practised at Brentford as far back as 1840.

Conover's Colossal Asparagus.—Allow me to say in reference to this Asparagus, that I can fully confirm what has been stated respecting its superiority over the old variety during its early stage of growth; but as Mr. Grieve says (see p. 415), that it does not maintain that superiority after three or four years' growth, I am anxious to know from those who have grown it for several years whether their experience confirms that fact. I planted several beds of it last spring, and certainly the growth this year is far superior to that in any bed one year planted which I have ever had. But one wants to see the beds daily, and compare the growth with more established beds, in order to note the difference. I did not plant any beds of the old variety under exactly the same circumstances; therefore, comparisons made in the case of a few growths would not be fair. Under ordinary circumstances I never cut any Asparagus from beds until the second year after planting when the plants are three years old, and then only a very little. But if the beds of Conover's Colossal increase in strength as much this year as last, they will be capable of producing a full crop next year, or two years from the date of planting.—G. J. H.

Forced Seakale.—What should be the average height of Seakale when properly forced under pots in the open ground? I am not satisfied with the growth of that produced in my garden; it very soon runs into long thin shoots, having but little substance.—L. L. [The average height of Seakale, when properly cultivated and forced under pots in the open air, should be, when cut, from 4 in. to 5 in. There is often too much fermenting material used in covering the pots to force it; this makes it grow too fast to become drawn, and not to be so succulent as it ought to be. The fermenting material ought likewise to cover only a certain portion of the pots in the beds at the time, so as to have a succession of heads ready to cut at the proper height. For the last two years I have grown and blanched the latest supply of Seakale in the open air in the following way:—At the end of autumn the crowns in the rows or beds of Seakale intended for the late supply are covered up with about 10 in. of dry sandy soil, and in the April and May of the year following a supply of crisp good-flavoured Seakale is cut from them. It is easily seen where to cut the Kale from by the upheaving of the earth; of course, such heads are cut first, and the earth is washed off before they are used.—W. TILLERY, *Welbeck*.]

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Rhubarb and Apple Tarts.—At this season Apples have lost much of their flavour, and are not at all agreeable in tarts by themselves. Out-door Rhubarb just coming in is in many too acid after eating that forced indoors. I have just had a tart consisting of Apples and out-door Rhubarb mixed, about half of each, and it was really excellent.—J. TAYLOR.

Bitter Cucumbers.—I would recommend "G. G." (see p. 429) to give his Telegraph Cucumbers a couple of thorough soakings with clear water. He may at any time know when they require water by simply cutting off a tendril and tasting it. These are always sweet when the plants are not suffering from want of water at the roots, but as soon as they begin to get dry there the tendrils commence to have a bitter taste, and the drier they get the more bitter the tendrils become and also the fruit.—JOHN CLARKE, *Coek*.

Mushrooms on a wall.—Perhaps your correspondent "V." (see p. 429), will favour an unsuccessful grower of Mushrooms with further information concerning the wonderful growth of Mushrooms from the face of a brick wall in Lord Lonsborough's gardens?—P. [The spaw penetrated the wall from a bed made against it on the other side about 6 ft. from the ground.]

NEW PLANTS, &c.

Cypella coerulea is a well-known and very beautiful warm greenhouse plant bearing blue flowers; it is a good addition to the six or eight species already known. Unfortunately its flowers are rather fugacious.—“Botanical Magazine,” t. 6213.

Ainsliea Walkeri.—A slender-habited composite plant from Hong Kong, bearing terminal panicles of bluish-white flowers, its stems, which are erect, being thickly clothed with dark green linear lance-shaped leaves 2 in. to 3 in. in length, and notched towards their apices. It is a weedy-looking plant, unsuitable for decorative purposes.—“Botanical Magazine,” t. 6225.

Dracocephalum altaianse.—A beautiful hardy perennial, of erect dead Nettle-like aspect, having oblong crenate leaves of a bright green colour, and axillary clusters of large tubular flowers, of a dense Gentian-like blue colour, spotted or dotted with red in the throat. It has long been known in this country, and was figured in Sweet's “Flower Garden,” ii., t. 57; “Gartenflora,” t. 855.

Hypoestes aristata.—This pretty South African shrub bears opposite bright green ovate leaves and axillary clusters of bright rose-lilac flowers towards the apex of the branching stems, the upper petal being distinctly spotted. It bloomed with Messrs. Veitch & Sons in 1874, and grows from 2 ft. to 3 ft. in height; but, for decorative purposes, small plants are best.—“Botanical Magazine,” t. 6224.

Allium ancep.—This pretty little purple-flowered Californian bulb, found on the Sierra Nevada portion of the Rocky Mountains, flowered with Messrs. Veitch and Sons in May, 1875. Its flowers, which are stellate, are arranged in dense semi-spherical heads, at the apex of flattened aciculate scapes, from 4 to 6 in. in height. It is said to be quite hardy in this country, and it certainly deserves culture on dry warm soils.—“Botanical Magazine,” t. 6227.

Dendrobium fuscatum.—A tall-growing, erect-habited species from the Eastern Himalayas, somewhat nearly related to *D. chrysanthum*. Its flowers, which are orange-brown in colour, are borne in pendent, eight to fifteen flowered racemes, from near the apex of the leafy stems. The lip is densely papillose in front, and of a deep orange-yellow colour, having two conspicuous crimson blotches, one on either side of the disc. The plant is a showy one, and well deserves culture where *Dendrobies* are grown.—“Botanical Magazine,” t. 6226.

Odontoglossum Inseleyi leopardinum.—The old *O. Inseleyi* has long been known in gardens as an attractive winter-blooming plant, its main attraction being a very bright golden yellow crimson-dotted lip. This new form, however, has much deeper and brighter coloured sepals and petals than in the old variety, the bars and blotches being of a rich cinnamon-brown colour. It is one of *M. Roezli's* discoveries in Mexico, and has been distributed in this country by Messrs. Backhouse & Sons, of York. It is a distinct and well-marked plant, well worth culture.—“Gartenflora,” t. 856.

Sedum pulchellum.—This is a pretty, slender-habited, North American plant, and is popularly known as the “Bird's-foot Sedum.” Its slender stems are 8 in. to 10 in. in length, clothed with short fleshy leaves about an inch in length and hastate at the base. The inflorescence is branched, the four-petaled flowers being of a delicate rose-lilac colour, having deep reddish-brown stamens. It must not be confounded with *S. sexangulare* and *S. Lydium*, two plants which we are told, are not unfrequently grown for in English gardens. It is a graceful and most desirable plant for rock-work or the wild garden.—“Botanical Magazine,” t. 6223.

Moore's Rural New Yorker.—There is much evidence of great horticultural progress in America, which must be welcome to lovers of gardening everywhere. Thus we see that popular journal, “Moore's Rural New Yorker” becoming more and more devoted to horticultural pursuits, and now Mr. A. S. Fuller and Mr. E. S. Carman, two horticulturists of the best school, are appointed Editor-in-chief and Horticultural Editor. Mr. A. S. Fuller is the author of the always interesting and instructive “Diary of Rural Life” (mostly, however, concerned with gardening), which has long been one of the best points in the journal. Mr. D. D. T. Moore, who founded the journal, now retires through ill-health. We believe that the influence of two such able horticulturists, exercised through so widely circulated a journal, cannot fail to have a healthy effect on the progress of our art throughout what we believe is to be horticulturally, as well as otherwise, the “Greater Britain” of the future.

SOCIETIES AND EXHIBITIONS.

ALEXANDRA PALACE.

MAY 5TH AND 6TH.

AMONG plants shown on this occasion the Roses in pots from Mr. Charles Turner, of Slough; Messrs. Lane & Son, of Berkhamsted; and Messrs. William Paul & Son, deserve especial notice. Those from Messrs. Lane, although not large specimens, were unusually fresh and beautiful. Mr. B. S. Williams contributed several groups of select Ferns and ornamental foliaged and flowering plants, among which we remarked a fine specimen of *Aotus gracillima*, an old greenhouse plant now rarely seen at exhibitions. It has long, gracefully-curved, Hovea-like branches, clothed with dark Epacris-like leaves and closely-arranged orange-yellow flowers. It well deserves culture, either for ordinary decoration or for purposes of exhibition. A plant of *Eriostemon cuneatum*, in the same group, was much admired, being fully 5 ft. in diameter and covered with white star-like flowers. Messrs. Cutbush & Sons, of Highgate, staged, among other plants, a pan of the old dark-leaved white-flowered *Primula Monroi* in capital condition. This is a very beautiful species, and one well worthy of culture by all lovers of hardy herbaceous plants. Mr. Charles Turner sent an attractive group of Show Pelargoniums and a select collection of *Alpine Auriculas*. From Mr. Ware, of Tottenham, came a collection of Pansies.

Certificates of Merit.—These were awarded to the following new florists' flowers:—

Auricula Chas. Lidguard (C. Turner, Slough).—A very attractive Alpine variety, described in our last week's issue.

Auricula Wm. Bragg (C. Turner).—A distinct-looking Alpine variety, with extremely dark crimson, almost black flowers, having a rich golden-coloured eye. It is a “pin-eyed” variety, but is none the less attractive on that account. We were glad to see this absurd distinction broken down publicly for the first time, especially in the case of a variety so distinct and beautiful as this was.

Azalea indica var. Apollo (C. Turner).—A large white-flowered variety, having greenish spots on the upper petals, and irregular scarlet streaks. It is very floriferous, but not any advance on existing kinds.

Pelargonium grandiflorum var. Ghpsy (C. Turner).—A compact habitated variety, having dark velvety crimson-scarlet flowers, the upper petals being nearly black, margined with vermilion.

P. grandiflorum var. Diplomatis.—A robust and free-blooming kind, having bright rosy-scarlet white-eyed flowers of good form, the upper petals being of a rich velvety-crimson, nearly black colour, edged with vermilion.

The classes were not well filled as a rule, but all traces of thinness, owing to the paucity of exhibitors, were removed by the excellent groups of decorative plants from the collection of the Palace Company, which were disposed in various parts of the Great Hall with excellent effect. A list of the prizes awarded on the occasion will be found in our advertising columns.

OBITUARY.

LOUIS VAN HOUTTE.

WE announce with much regret the death of the most famous horticulturist in Europe, M. Louis Van Houtte, of Ghent. News of this only reached us a very short time before going to press, so that our present notice must be brief. M. Van Houtte's life and labours must be of great interest in relation to horticulture, and we hope to give them proper notice in due time. It is scarcely necessary to inform our readers that Van Houtte was the principal nurseryman in that city of nurserymen, Ghent—that with his nursery was for a long time incorporated a national school of horticulture, which was an excellent training school for young men. He was also in early life, we believe, distinguished as a botanical traveller; and he was an enthusiastic lover of plants, apart from monetary considerations. His establishment at Ghent was universally allowed to be the finest of the kind in Europe. He was the editor and proprietor of that excellent magazine, the “Flores des Serres et des Jardins de l'Europe.” Ailing for a long time past, his desire to see his friends and their plants at the late Brussels Show led him, against the advice of his friends, to make the journey from Ghent to Brussels, which it is supposed accelerated his death, which occurred in his sixty-sixth year, on Tuesday last, the 9th instant.

MR. WILLIAM CUTBUSH.—We have also to record the death of Mr. Wm. Cutbush, nurseryman, Barnet, which took place on the 4th instant, some what suddenly, at Brighton, where he had gone for the benefit of his health. For many years he was a conspicuous exhibitor at our great London shows. He was well-known and highly-esteemed by a large circle of friends, to whom his death is a sad loss.

Notice.—A constant reader who sends blooms of *Adonis vernalis*, “J. H.” “L.L.” “Wycombe,” and others are reminded that we never name plants unless the full address of the sender be given. The printed name of a plant can be of no interest to any but the person who sent it, and therefore we always reply by post upon receiving the address. The *Camellia* sent by a correspondent, whose address has been mislaid, is *C. Corallina*, a kind sent out some years ago by Mr. Chandler.

"This is an art
Which does mend Nature; change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE RAMANAS ROSE A CONTINUOUS BLOOMER.

IN reference to *Rosa rugosa*, well figured in No. 234 of THE GARDEN, I write to draw attention to a character of the plant not alluded to in the article accompanying the figure. With me this *Rosa* continues to produce flowers on the young wood from the end of May to October or November, when it is checked by the autumn frosts. This is an important character, and should be held in much estimation by those who may feel inclined to use the *Rosa rugosa* as a good species with which to try experiments, by crossing it with other species or varieties of the *Rose*. The plant of the original pink-flowered variety is from 3 ft. to 4 ft. high, bushy, and during the summer densely covered with its beautifully corrugated and dark green leaves. It grows in a cool situation, facing the north, planted in a mixture of rich loam and bog, and within a few feet of a tall wall, running east and west. The flowers are produced very freely, sometimes singly, but often in clusters, on the strong shoots. From this bush I have measured flowers 4 in. in diameter, and I find that its large and handsome fruit generally contains a considerable number of perfect seeds. Much has been said and promised about perpetually flowering *Roses*, but very few are so among those called Hybrid Perpetual, most of which only produce a few flowers during the autumn. To obtain a race of really perpetual *Roses*, with large finely petaled flowers, meeting the critical requirements of the *Rose* grower, is still a desideratum, but we should not be satisfied there, as I feel by patience and careful crossing we shall have the large and fine flowers, ere long, combined with rich perfume, large, glossy evergreen leaves, and the bushy as well as the rampant growth. Is it asking too much of horticulturists to try and produce such *Roses* as I have sketched out, seeing what they have already accomplished in the improvement of the *Rose*, and knowing, as they must well do, that *Roses* are now easily to be had, which have one or more of the qualities upon which I set store. The white variety of *Rosa rugosa* I grow, thanks to Mr. Ware, of Tottenham, but my experience of it is limited. It is now producing leaves freely like those of the original species, and they appear to be of the same beautiful character. W. W. S.

Worthing.

DOUBLE DAISIES.

As "A. D." (see p. 428) asks for a little more information on this subject, I will attempt to furnish it. In the first place, I think that the naming of Daisies, otherwise than calling them red, white, quilled, or the reverse, is simply ridiculous; every nurseryman, indeed, seems to give them names of his own; for only last season I received the old Mottled Daisy under the name of the Prince of Wales. I grow Daisies extensively, and perhaps have, scattered over my garden, some thousands of them of all colours now in full bloom, and were they to be at once removed, a serious blank would be the result. I believe I have grown from twenty to thirty tolerably distinct Daisies, double and single; and, if "A. D." will communicate with me, I think I could add to his collection. Having alluded to the old Mottled Daisy, I may say that it is the earliest and the hardest of all Daisies. I saw masses of this, or a similar Daisy, at Battersea Park a few seasons ago, but it was not at all effective; none of the grey Daisies are so, except when contrasted with the old blood-red kind. I possess a very superior double-quilled sort of this colour, which was sent me under the name of Defiance. Of pink Daisies, including flesh or rose coloured, there are many fine kinds, both quilled and flat-petaled, and owing to some of the latter having incurved centres, the under sides of the petals are brought up, thus giving the flowers a pretty two-coloured appearance. I have "A. D.'s" *ranunculoides* or *ranunculiflora*, a kind of no great

merit. I possess a charming rose or pink quilled Daisy of medium size, which I consider the most perfect quilled kind known, being good in every point. I know nothing of its origin; it seems to come nearer to "A. D.'s" pink Queen than anything else with which I can compare it. My best white Daisy is a very large, entirely white variety with flat petals; this, however, shows the centre late in the season. I take it to be the Giant White. A visitor, on seeing it the other day, remarked that it looked more like a Dahlia than a Daisy. I bought it the other day, thinking it was something new, under the name of Dickson's White. The Large Quilled White is a fine kind as far as size is concerned, but owing to its being quilled, it is dull in colour. I have, or had, what I take to be "A. D.'s" Queen of Whites, a globular Daisy—in fact, a perfect ball. I have also a miniature white Daisy, quilled with a tinge of blue or purple. These miniature Daisies make neat edgings. In addition to the above, I have many promising seedlings. The red Daisies are perhaps the most effective of all, but a flat-petaled red Daisy is still a desideratum. I have all "A. D.'s" red kinds except the one called Bacchus, at least, I do not know it by that name; but I have a very fine crimson of this class, named by the sender—Mars, the latest blooming Daisy with which I am acquainted. The old Crown Daisy is much cultivated in cottage gardens in Lancashire, where, in damp soils, it grows to an enormous size; but it does not associate well with any other variety. I quite agree with "A. D." that the kinds called New Victoria Daisies are in no wise better than the old Crown, nor yet equal to it; indeed, I have discarded the whole of them. There is a blue-coloured Daisy (*Bellis rotundifolia corulea*), but I have not seen it. Those who wish to grow Daisies in perfection should divide them every year, not later than August, as single crowns produce by far the strongest blooms. They like a rich damp soil, and will bear gentle forcing, that is, they may be forwarded in a cold frame; and pans, or shallow baskets, furnished with from one to three dozen various kinds tastefully mossed over are charming objects in February or early in March. The combinations that may be effected by means of these hardy early flowers are endless. Certainly no plants furnish even the worst gardens with such a mass of permanent colours in the earlier part of the season as Daisies, and nothing but prejudice prevents them being planted in our squares and parks by the million. THOS. WILLIAMS.

Bath Lodge, Ormskirk.

SELECT CROWFOOTS.

THERE are many worthless and weedy subjects among Crowfoots, but we may pick out several choice gems which should be seen in every collection of hardy plants. Taking them alphabetically, we come first to *Ranunculus acrifolius*, a kind with single white flowers, which grows 18 in. in height, and is of graceful habit. The double form (known as *Pair Maid* of France) is more commonly seen, and is a pretty plant, with double white Camellia-like blossoms. *R. acris flore-pleno* (the old Bachelor's Buttons of cottage gardens) is another useful border plant, with double yellow flowers. Of quite a distinct habit is *R. amplexicaulis*, a species with smooth, glaucous, undivided leaves, and pure white flowers with yellow centres; it is a most beautiful plant; it grows about 9 in. in height, and prefers a cool sandy loam. *R. bulbosus flore-pleno* is of about the same stature as the last, with double yellow flowers; its leaves are three-lobed and much divided. *R. bullatus* is a fine showy plant, and was mentioned in THE GARDEN of last week under the name of *R. speciosus*. It does not grow more than 6 in. in height, and has large, double, orange-yellow flowers, very like those of the double-flowered Marsh Caltha; it also goes by the name of *R. grandiflorus*. *R. glacialis*, an Alpine species, does not grow more than 2 in. or 4 in. in height, and requires some little care in cultivation, doing best in light gritty soil kept moist during the heat of summer. When in good condition its pretty white flowers produce a very pleasing effect. *R. gramineus*, another useful subject worthy of a place, has Grass-like leaves and yellow flowers about 1 ft. in height. *R. montanus* makes a good dwarf companion for *R. glacialis*, though it grows more freely in any light soil. It is a pretty little yellow-blossomed plant. *R. parnassifolius* has Cyclamen-like leaves, roundish heart-shaped, and flowers resembling those of *R. amplexicaulis*. Though a beautiful plant I have always found it a very ticklish subject to deal with, and difficult to keep; at present I regret to say that I have not a single plant of it. *R. Rouani* is a

vigorous and showy subject, with large, glistening, yellow flowers; it grows about 18 in. in height, and makes a useful addition to the second line of the mixed border. *R. rutifolius* has (as its name implies) very much divided Rue-like leaves, and white flowers with dark yellow centres. As it comes from the highest parts of the Alpine ranges near the snow limits, it probably requires the same treatment as other high Alpine plants, though I have found it do fairly well in the mixed border in light soil, with a few flints plunged about its roots. *R. Thora* is a distinct kind with yellow flowers; it grows 9 in. high, and has pale green leaves, shaped like those of the Coltsfoot; *R. uniflorus*, a pretty little plant with white flowers and deeply divided leaves, is worthy of a place in the front line of a mixed border. I have had many other varieties of the Ranunculaceae tribe, but have discarded all but the above, owing to their weedy appearance and similarity of bloom to that of the common Buttercup. Those just mentioned will be found worthy ornaments of every collection of herbaceous plants, and they nearly all succeed perfectly in ordinary borders.

Oxon.

TRIAL OF FUCHSIAS AT CHISWICK IN 1875.

These were grown under glass, and consisted of young plants shifted on into moderate-sized but rather small pots. The following, which were examined just when they had reached their best condition as to bloom, received first-class certificates.

I.—Whitish tube and sepal; red or purple corolla.

1. *Annie* (Veitch & Sons).—Of rather bold growth, but dwarfed in habit. Flowers with short bluish tube; reflexed, flesh-coloured sepals, and large, open, carmine-red corolla. A free-flowering sort.

2. *Brilliantissima* (E. G. Henderson & Son).—An erect-habited rather vigorous-growing variety. Flowers with a greenish-white tube, reflexed sepals, and a dark crimson corolla; very fine in colour, but rather small. Certificated on account of the habit of the plant, which was excellent; in the way of the variety called *Lustro*, but superior to it.

3. *Josephine* (E. G. Henderson & Son).—A variety of dwarf and stocky but rather vigorous growth. Flowers with long bluish tube, and short reflexed sepals, and bright rosy-pink corolla.

4. *Marginata*.—Of free bushy habit, and a free bloomer. Flowers with short bluish-white tube and reflexed sepals, and a rosy-tinted corolla with crimson margin.

5. *Schiller*.—A finely-shaped, free-growing, bushy plant, of drooping habit. Flowers with a bluish tube and spreading sepals, and a purplish corolla. The flowers are larger and better than those of *Rose of Castile*, which they resemble in colour. The habit is excellent.

6. *Starlight* (Veitch & Sons).—A free-growing and free-blooming variety of excellent habit. Flowers large, with long white tubes and sepals, and long, bright, rosy-lake corolla. One of the very best of the pale-coloured species.

7. *Water Nymph* (E. G. Henderson & Son).—A dwarf, free-growing, bushy-habited variety. Flowers with bluish tube and straight sepals, and a crimson corolla. A very desirable variety.

II.—Scarlet tube and white corolla.

8. *Alexandrina* (Veitch & Sons).—A slender, drooping, free-growing, and exceedingly bright and attractive sort. Flowers with short bright red tube and reflexed sepals, and a fine white corolla.

9. *Mrs. E. Bennett*.—A free-blooming, free-growing, erect-habited variety. Flowers with very short red tube and long spreading sepals, and a very large spreading white corolla. Very distinct and fine.

The certificates already awarded to the following varieties in this section were confirmed—namely, to *Conspicua*, *Puritani*, and *Pursuit* (singles), and to *Enchantress* (double).

III.—Scarlet tube and purple corolla.

10. *Empress of Germany*.—A variety of dwarf, bushy habit, dense, free-flowering, and ornamental. Flowers with a short tube and reflexed sepals of a coral red, and a large, spreading, purple corolla.

11. *First of the Day* (E. G. Henderson & Son).—A variety of a dense, bushy, free-flowering habit. Flowers with a short coral-red tube, small reflexed sepals, and a large, bold, purple corolla.

12. *Inimitable*.—A variety of dwarf and free habit and ornamental character. Flowers medium-sized, with a coral-red tube and spreading sepals, and an expanded, violet-purple corolla reddish at the base. It is something in the way of *Empress of Germany*.

13. *Wave of Life* (E. G. Henderson & Son).—A variety of weak and drooping but dense habit of growth. Flowers with short tube and broad reflexed sepals of a brilliant coral-red and a large, long, spreading, dark purple corolla.

In this group the certificate previously awarded to *Commander* and to *Noblesse* were confirmed.

IV.—Scarlet tube, double purple corolla.

14. *Champion of the World* (F. & A. Smith).—A loose-habited variety, with long weeping branches, and well adapted for furnishing a pillar or rafter in a greenhouse. The flowers are immensely large and full double; the tube and sepals coral-red, the latter tipped with green; the corolla purple, expanding to nearly 2½ in. in breadth. It is the largest-flowered of all the double red Fuchsias.

15. *Mr. Lyndoe*.—A free-growing variety with very large flowers, of which the sepals are erectly reflexed, and of a pale red, and the corolla bold but somewhat irregular, and of a deep purple.

16. *Prince Leopold* (Veitch & Sons).—In this variety the plant is of a bushy, drooping habit and free. Flowers with a short tube and reflexed sepals, and a dark purple, compact, double corolla.

17. *Triumphant* (Veitch & Sons).—A variety of rather spreading growth, and tolerably free-flowering, altogether an exceedingly promising sort. Flowers with a slender tube and erect palish red sepals; the large, full, dense corolla of a rich deep purple. The individual flowers are exceedingly fine and well formed.

Of this group the variety named *Marksman* had the previous certificate confirmed.

V.—Pink tube and purple corolla.

18. *Hugh Mollen* (Veitch & Sons).—A variety of free and vigorous but bushy, drooping habit, well adapted for furnishing a pillar or rafter, being not only showy but distinct in character. Flowers large, with a long, slender pink tube and spreading green-tipped sepals, and a bold and spreading purple corolla. A very effective, ornamental variety.

VI.—Variegated leaves.

19. *Aucubæfolia* (E. G. Henderson & Son).—A very ornamental variegated-leaved variety, having greater merit from this point of view than from that of its flowers. The leaves have a large creamy-white and conspicuous central blotch, and when this variegation is well marked the plant is very handsome; but it is a form of variegation very apt to run out unless care be taken in the selection of cuttings. The flowers are freely produced, and have a long red tube and sepals, the latter not being spread out or reflexed. The certificate was given for the variegation.

20. *Sunray* (G. Smith).—A beautifully variegated Fuchsia, the finest yet sent out, with red, variegated foliage, which is quite ornamental. The flowers have red tubes and sepals, and a purple corolla. It was certificated for its variegation.

T. MOORE.

SUMMER TREATMENT OF CHRYSANTHEMUMS.

WHEN the month of May active work begins amongst Chrysanthemums; early-struck cuttings should now be in 8-in. or 9-in. pots and making rapid growth. If it be desired to grow handsome specimens with fair-sized blooms as well, the plants should be stopped until from eight to twelve stems are obtained, according to the variety and strength of each plant, each stem so produced being allowed to grow on and to bear a single flower. Search the plants carefully for green fly, which is sure to appear sooner or later, and apply a solution of soft soap to destroy it. Great care should be taken that the solution is not too strong or the young shoots will be injured, and it is always better to repeat the dose frequently than by one overdose to risk the year's prospects. The health of the plants is much improved by syringing them after a hot day; and, indeed, the surface of the ground all round them should always be kept moist in dry weather. An occasional syringing with weak soot-water is very beneficial. When the plants have been put into their blooming-pots it is very desirable that they should be partly plunged, but plunging is not of such importance before that, as of course, not having been allowed to become pot-bound, the roots run less risk of being burned. My practice is to set the plants in the sized pots in which they are next to be potted, which of course shades the inner pot from the sun. To grow Chrysanthemums properly they should stand in as open a situation as possible, where they will have the sun all day, but

it is most important that they should be sheltered from strong winds. The soil should consist of turfy loam, which may be used quite fresh, with a fourth or fifth part of horse-manure. In order to prepare the manure, it should be collected fresh from the stables until as large a quantity as is needed to pot all the plants in their blooming-pots is obtained; it should then be thrown into a heap and left until the violent heat has passed off, when it should be worked through a sieve until it is quite fine, in which state it is fit for use. For previous pottings, ordinary old hot-bed manure will answer, but the other should be used for the final potting, as it will produce the finest blooms. When the manure has been properly mixed with the soil, the compost has, to the touch, a sort of alkaliness, and is admirably suited for the fine roots of the *Chrysanthemum*. The following are a few of the finest sorts in the large flowering section:—Golden Queen, Queen of England, Jardin des Plantes, Golden Boverley, White Beverley, Empress of India, Guernsey Nugget, Abbé Persaing, Progne, Glück, Lady Talford, Golden Ball, Venus, Prince of Wales, and Lady Hardings. B. H. MARGRETS.
Finedon, Wellingborough.

Mossy Saxifrage.—Is the plant thus termed, which has been recommended in THE GARDEN for beds in which bulbs are planted, the same as the plant sometimes called "Dove-dale Moss," in consequence of its growing wild in Derbyshire, in the well-known picturesque locality of Dove-dale? I have one species of this so-called Moss, the flower of which is white, and two or three blossoms are borne on one stem; and after flourishing for a year or two over stones which border a flower bed, it seems to die off. There is one of similar appearance but with much larger flowers, which in some localities grows so rapidly that there are annually sufficient clippings to plant many beds (at least such is the account given of it to me by a friend). Any information respecting the Mossy Saxifrage recommended in THE GARDEN for bulbs would be of much service to the inquirer, and also whether it is intended to be for a permanent bed with the bulbs, or to be removed when they are removed?—L.L. [The plant referred to by this name in THE GARDEN is usually Saxifraga hypnoides, or one of its numerous forms or allies, of which there are many in cultivation. They are all very hardy, but sometimes old tufts perish—usually from drought. It may be employed for permanent beds or otherwise; it grows very freely, and is increased by division. The tufts are sometimes full of rootlets above ground; therefore it is easy to increase the plants by pulling the green part to pieces and planting them immediately.]

Pelargonium inquinans "Old Giant."—Twenty years ago this, at that time, popular plant used to be trained on the back walls of greenhouses and conservatories. It blooms constantly and freely if planted in a sunny situation, and attains a height of from 15 ft. to 20 ft., the stems being as thick as one's thumb and the foliage proportionately large; the flowers, which are vivid scarlet, are borne in immense trusses. Of this I recently saw a specimen in Mr. Heriot's conservatory at Highbate, where its habit of blooming perpetually is much appreciated. Cuttings of it taken off during the summer root and grow freely, and if standard or pyramidal grafted plants be desired, this makes the best of all stocks on which to place the more delicate varieties.—B.

Hardy Evergreen Ornamental Climbers.—This class of plants is comparatively rare, and I have often been surprised that the beautiful evergreen creeper, by some persons called Smilax, which grows wild in such profusion on the shores of the Mediterranean in many localities, and especially near Nice, has not been introduced into British gardens, whereas it seems to be almost unknown. Its leaves resemble those of the Holly in texture and polished appearance, and some plants have many more prickles than others, and there is also a difference in the form of the berries, which are always bright scarlet. It grows between rocks and stones in apparently exposed places, and in poor soil; but it is a most beautiful plant, and if cultivated, might possibly be rendered available for growing up trees as well as walls; but in its native state it falls over small bushes or rocks in large masses. Some berries of it which I brought to England became mouldy, and never germinated.—L.L.

New Zealand Flax in Flower in Scotland.—A large plant of New Zealand Flax (*Phormium tenax*) is now in bloom at Mayfield, Falkirk, and I have every reason to believe that it will ripen seed, for a number of the flowers from 250 to 300 flowers about 3 in. long and 1 in. wide; very strong, bearing the sepals dark brown; the pistils and stamens rise nearly an inch above the petals, and the stamens are thickly laden with pollen. Its general appearance is striking and majestic. It is the best specimen of New Zealand Flax that I have ever seen in Scotland.—A. LORIE.

THE KITCHEN GARDEN.

SEED-SOWING IN WET SEASONS.

It is never advisable to go upon ground when it is wet and sodden; but when seed-time properly so called is about ended for the season, and the ground is still wet, such considerations have to be put on one side, and one has to adapt his practice to the exceptional state of things. To tread Onion ground when the soil is the least wet is of the height of indiscretion, for it causes it to bind like clay, and when dry weather sets in it becomes a network of deep fissures, and it is altogether in a most unattractive condition for the plants, which never come away or grow as they should. The most miserable crop of Onions I ever saw were sown under these conditions. This season I simply turned the ground over with forks, and afterwards scuffed the surface over with wooden rakes to level it, drew drills, sowed the seed, and covered it over by hand with dry soil from the sheds, leaving the finishing touches with the rake to be done in dry weather. Raking the surface of a seed-bed when the soil is wet is worse than digging it in that condition, for it rolls it into nodules, which the first shower of rain runs together into so impervious a crust that the seed cannot push its way through. The vegetable that suffers more than any other, however, when sown in a cloggy soil and covered in with the same material, is the Turnip. The young plants come away sluggishly, and are almost sure to fall a prey to the fly. Under such circumstances the sowing should be done as the ground is dug, no raking should be attempted, and the seed should be covered by hand, like the Onion, with dry light soil of any kind. Treated in this way they do well enough, and the ground can be stirred deeply between the rows on the first favourable opportunity. All small seeds, such as those of Lettuce, should be treated in the same manner. Peas and Beans should just have the soil drawn over them as sown, without any raking or patting. French Beans, if the soil be heavy, do much better if covered like Turnips; so also does Beet, and indeed any large seeds that do not need to be covered deeply. After the crops are fairly above ground, the adverse conditions of seed-time may be greatly compensated for by surface-stirring, doing it deeply with the hack or Dutch hoe, and when practicable by mulching. I have had to deal with soils so heavy and tenacious that they never "fell" kindly during the whole summer, if the ground were dug when wet; the sun simply baked the clods into lumps like pieces of brick. Planting any of the Cabbage tribe in such a soil was a difficult operation, and they made little progress for weeks afterwards, unless mulched with some loose material such as short Grass, which is always plentiful, when they did not appear to suffer much. There is less to be feared, however, with the seed-bed in wet seasons than with those crops which require transplanting. The roots of seedlings find their way into the soil when once they get a start; but transplanted subjects take most unkindly to the ground when the soil is lumpy and wet. Cauliflowers are almost sure to "button," Lettuces to "bolt," and few things do well. Moving with good balls in all cases, and planting without squeezing the soil about the roots, and surface-stirring with the hoe afterwards, is the only plan. I am, of course, not speaking of soils which after a period of drought have just been soaked with a good fall of rain, for then the soil is in the best condition for planting, but of soils, and particularly heavy ones, which are in a state of saturation. CHEE.

RHUBARB CULTURE.

RHUBARB will grow on many kinds of soil, but the richer and deeper they are the finer will be its quality, and the larger its size. The situation should also be moderately dry, or made so by drainage. It will grow in clay, peat, or the bog-earth of the Fens. Perhaps, had it a choice, it would elect, like most other garden plants, a turfy loam, leaning to clay rather than sand. When the leaves get fairly into growth, it needs some strong stimulant to keep them going. The larger the leaves of one season the stronger will be the crown for the next; hence the importance of rich feeding all through the growing season. It is a good plan in small gardens to plant Rhubarb near the dépôt for house sewage, so that it may be nourished with strong waters as well as rich solid manure; 4 ft. at least, of a rich root-run should be provided for it. For new plantations the ground should be thoroughly trenched, and the manure carefully incorporated with it. Its productive force should be kept up afterwards by an annual dressing, from 4 in. to 6 in. in thickness. No plant is more easily increased, and multiplied than Rhubarb; plants of two or more years old seed freely if permitted to do so. Unless seed be required, however, they should not be allowed to do so, as seed-bearing weakens the crowns. The seeds ripen about the end of September, and may be sown at once in shallow drills a yard apart, or they may be sown in February. As soon as they are well

up, thin the plants to 18 in. or 3 ft. asunder, according to the size of the plant and the intention of the cultivator. If intended to remain where they are, a yard apart is close enough—indeed, too close for the Victoria variety. Some, however, prefer rows 2 ft. apart, and thinning the plants to 1 ft. only the first season; then in the October or February following fresh ground is prepared, and the Victoria transplanted at distances of from 4 ft. to 6 ft. by 4 ft., and the Defiance 3 ft. by 18 in. or 2 ft. The best plan is to sow Rhubarb where it is to remain, as it forms immense roots that are easily broken, and to break it to injure more or less. Nevertheless, a very common mode of propagating Rhubarb is by root division. The huge stool or fleshy root is sliced into as many portions as there are crowns to it with a sharp knife or spade, and each slice forms a new plant. This is rather a barbarous mode of increase. Gathering Rhubarb, and when to cease gathering, are operations which require more attention than they generally receive. In gathering, the proper method is to give the leaf-stalk a twist outward, and a sudden jerk down at the same moment. From want of attention to this, many tear off the crown with the base of the leaf-stalk. Again, too many leaves should not be gathered at once. If a plant have only a dozen leaves, do not gather more than six of them, and let these be the lowest. As to the age of the stalk, that depends a good deal upon taste. Some prefer Rhubarb when the leaves are freshly unrolled, others when they are half-grown, and others when they are fully grown. Of course there is great waste if the stalks be gathered before they have reached their full length. I think Rhubarb is at its best just when the leaf has reached full size. It can hardly be too old for preserving, and is seldom gathered till the end of August for that purpose. As to the time of ceasing to gather Rhubarb, it should certainly be not later than August if the gathering is to be annual. This leaves but little time for the last leaves to ripen a crop of good crowns for the next year's crop, all the leaves removed have doubtless been a loss to the plant: they did much to weaken and nothing to strengthen it; it is only the leaves left on that recoup it for its loss in those taken off. Hence the importance of rich food to replenish the plant, and time for the maturation of the later growth; and I need hardly add that no weed must be permitted to grow at the expense of the Rhubarb plants. Grown as here briefly set forth, perhaps no crop yields a heavier or more profitable return than Rhubarb. D. T. F.

Planning a Market Garden for Horse Culture.—A market gardener writes to the "Evening Post" as follows:—Much labour may be saved by arranging the garden in long, narrow beds, running north and south, instead of irregular and dispersed patches. The fruit trees should be placed in rows so disposed that they, as well as other rows, can be cultivated readily and easily by horse and hand machines, of which there are several excellent ones. When thus arranged the garden can be well ploughed and harrowed by one horse without injury to the fruit trees or beds of permanent vegetables or herbs. It will be found very convenient to have broad plats of Grass at each end of the garden upon which the horse may be turned. These should be kept closely shaven with a lawn mower. Most of the sowing and planting may be done with a hand-drill, which, with arrangements to enable it to be used a weeder or a cultivator, can be procured for a small sum. These implements are a great relief to the labour of gardening, and prevent the necessity of much stooping.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

A Good Late Broccoli.—Where a really good late Broccoli is wanted both for size, colour, and flavour, Petersfield Late should be largely grown. It is dwarf in habit and one of the best self-protecting kinds with which I am acquainted. The colour now is as white as that of any Cauliflower. It is an excellent variety, and equally late as Eclipse, which forms a good comparison to it, but it is neither so white nor yet so self-protecting.—A. H. Thoresby Gardens.

Conover's Colossal Asparagus.—Like Mr. Peter Grieve (see p. 418) I find this to be more prolific than the common variety, and to be a year in advance of it when raised from seed. I had a small bed of it sown here on the 1st of May, 1874, on land which had only been prepared in the usual way for crops in general. Nevertheless, on the 1st of this month, I cut some good heads of a beautiful deep green colour. Conover's came in before the common kind with me this year.—G. Noakes, Mountfield Court.

Wood's Selected White Cape Broccoli.—Cape Broccolies have lately fallen into disrepute, but I find this one most serviceable for autumn use. Care should, however, be taken to sow it at a certain time, for, if sown too early, the produce is comparatively worthless. I generally sow a small bed of it the third week in May, and another the first week in June, and transplant, as soon as the young plants are large enough, to sheltered borders on which early Peas and Potatoes have been growing. Its heads are of medium size, solid, and beautifully white—quite equal, in fact, to those of Cauliflower—and in September and October they form a valuable addition to our list of choice vegetables.—J. Groom, Aekham.

NOTES OF THE WEEK.

— FOR some time past Mr. Noel Humphreys has been at work on a series of drawings of Alpine flowers—fifty in number—and representing the more important types of beauty among these flowers. The work has been a labour of love, and the result is a very charming series of drawings, quite unlike any we have before seen of these or like subjects. The plants are represented life-size and growing on or amid the rocks, cushioned in Moss or associated with their fellows. The whole established growth of the plant and its blossoms is shown, and not merely sprigs or flowers. The drawings are now mounted and arranged in a room in THE GARDEN Office, where any of our readers may see them.

— THE double form of the Ladies' Smock (*Cardamine pratensis*) is a pretty old-fashioned flower which we notice again coming into cultivation. It was shown in pots at the Aquarium exhibition the other day by Mr. Elliot, and was very pretty. The double Meadow Saxifrage (*S. granulata*) also formed an effective pot plant.

— THERE is a dark blue variety of the Wood Hyacinth grown under the name of *Scilla nutans violacea*, which is now one of the most beautiful of our hardy bulbs. It is cultivated by Mr. Parker at Tooting, and no doubt in other nurseries, and well merits a place on account of its colour.

— GARDENS round London have not for many years past, at this particular season, looked so woe-begone, nor the vegetation so parched and miserable, as during the present week.

— A FINE specimen of the Snowdrop tree is now in very great beauty in the gardens at Syon House. It is odd that such a lovely tree should be so seldom seen in gardens generally.

— THE Rev. Canon Hole informs us that the Roses in pots shown at the Westminster Aquarium this week by Mr. Turner, Mr. George Paul, Messrs. Lane, and others, were, on the whole, the finest he had ever seen.

— IMMENSE quantities of Asparagus are being received in the London market, both from the neighbourhood of Paris (*Argenteuil*) and neighbourhood of Toulouse. The Paris "Grass" is the finest and usually blanched; the Toulouse samples are good, and large, and green for some inches.

— M. ERENS, formerly superintendent of the Paris City Nurseries at La Muette, near Passy, has been appointed Director-General of the horticultural and agricultural works of the Maharajah of Kashmir, and has just left for that famous valley in the great mountains.

— THE various hardy herbaceous Spurges (*Euphorbia*) now in bloom, and mostly at present confined to botanic gardens, are particularly suited for the wild garden, where their distinct, greenish-yellow tops would furnish pleasing effects at this season. With a few exceptions they are not so suitable for borders.

— THE rare and beautiful *Eritrichium nanum* may now be seen in bloom at Messrs. Hooper's, Covent Garden, a singular fact, seeing that it is so scarce in our gardens. It is a charming Alpine plant, closely allied to the Forget-me-nots, for which at first sight it might easily be mistaken. Though little more than 1 in. in height, it is a mass of lovely blue blossoms.

— THE new *Odontoglossum vexillarium* appears to be the most floriferous of all the species. Messrs. Veitch & Sons have a plant of it now in flower bearing ten strong spikes, and Mr. David Thomson, of Drumlanrig, writes to say that he has a plant of it which has produced thirteen flowers from one pseudo-bulb. Among Messrs. Veitch's plants are several in which the rosy colouring is very soft and delicate, and these, as to our mind, far more beautiful than the darker-coloured varieties.

— A MEETING of the Executive Committee of the International Horticultural Exhibition and Botanical Congress of 1886 was held on Wednesday last, May 17, at the Royal Horticultural Society, South Kensington, at which it was unanimously resolved that it is desirable to institute a similar exhibition in London in 1879, provided that a suitable site can be found, and a provisional committee, consisting of the members of the former committee (with power to add to their number) was instituted for the purpose of taking the necessary steps. The meeting was quite of a tentative character, and another will be shortly held for the purpose of eliciting the opinions of horticulturists in general on the subject. The Horticultural Club, 3, Adelphi Terrace, Strand, has offered its meeting-room for the purposes of the committee meetings, &c. The chairman of the provisional committee is Dr. Masters, F.R.S.; the secretary, Mr. Thomas Moore, F.L.S., Botanic Gardens, Chelsea, to whom communications may be addressed.

THE INDOOR GARDEN.

CUT FLOWERS OF CHINESE PRIMULAS.

I FIND these very serviceable during the winter months. We have used them largely during the past season, and I know of few plants that will yield a greater quantity of bloom from a given space. Our earliest sowing is made in the beginning of March, and as soon as the young plants are large enough to handle, we pot them off into pots singly, using a light rich compost. In a moist growing temperature, of about 60°, shaded from bright sunshine, they make rapid progress, and require successive shifts into larger pots as they progress in growth. We give them a final shift into 6-in. pots in June; for, although they may be grown so as to make very large specimens by using large pots, I find the best results from moderate-sized ones well filled with roots. During the summer months, we keep them in cold frames in a bed of coal ashes kept moist, and shaded, as they do not like to be over-watered, but if the drainage be good, there need be little fear of their damping off when well established. All blooms should be pinched off for a time, as soon as they appear, in order to induce the development of lateral crowns, and thus treated when taken into an intermediate house about the end of September, they quickly form large masses of flower, and as specimens for vases few plants are more effective. As small plants are, however, the most serviceable for general decorative purposes, we employ the bloom of the largest plants in quantity, in a cut state, for dinner-table decoration, or for any flat kind of floral arrangement which we may have, as scarcely any flowers look better under artificial light than those of red and white Primulas. A few spikes of them in shallow glass baskets, in connection with any other choice flowers, make a beautiful table ornament. I find the kind called Russel's Pyramid to be an

excellent variety for general purposes; although these Primulas grow freely in a cold house, they are much more satisfactory in a temperature of about 55°; under such circumstances they continue to send up a succession of flower-spikes for a long period. Chinese Primulas are largely grown for the London markets, and where that is the case two or three sowings are often made in one season—the first early in March, the second at the end of April, and the third at the end of

May. Anytime in May will be early enough if they are not wanted in bloom until Christmas; but if required in October and early in November, they must be sown in March, in order to secure good strong plants. To get the seed up successfully market growers adopt the following plan:—They sow in boxes instead of in pans, as is usually done, as it is found that the seed hardly ever comes up round the edges of the pans. The reason is simply this, the pan absorbs the moisture from the soil, and consequently the seed gets dry, and if once it gets thoroughly dry after it has been soaked through, it never vegetates afterwards—a result which has been noticed over and over again. Private growers, who have in general only a small quantity of seed, are apt to sow it in a small pan, the result of which is, in many cases, failure in raising the seed. If sown in a box one does not run so much risk, as the box does not absorb moisture so readily as pans. Some sow on very old rotten manure, at least three or four years old, moistening it before sowing.

When sown a little silver sand is sprinkled over it—barely enough to cover it. J. GROOM.

PRITCHARDIA FILIFERA.

THIS Palm, of which the annexed is a representation, is one of the most beautiful of the handsome family to which it belongs. All who saw it at the International Exhibitions of Vienna, Florence, Ghent, Louvaine, &c., will remember its remarkably fine appearance and

Pritchardia filifera.

the admiration which it excited. It grows farther north than any other of the Palm tribe, its native habitat being the banks of the Colorado, in the province of Arizona, in New Mexico, where it bears the winter frosts without injury. It is excessively graceful in appearance, long white filaments falling from its palmate leaves, giving them the appearance of being furnished with plumes. This variety ought to occupy a conspicuous position, not only in private collections but also in those of public gardens. It will be found to form a good substitute for *Latanias*, *Phoenixes*, and similar Palms, of which amateurs are rapidly beginning to get tired. In the south of Europe it is perfectly hardy, but in more northerly climates it will succeed best under the protection of an ordinary conservatory or greenhouse. A. Ducos.

HOME-GROWN LILY OF THE VALLEY FOR FORCING.

We are at present very much dependent upon Continental growers for our supplies of Lily of the Valley for forcing. The trade in these roots has increased very much during the last few years, owing, no doubt, to the popularity of the plant, for it is second to none for general decorative purposes. Imported clumps of it are usually excellent, and produce frequently a well-furnished spike of flowers to every bud. I do not know exactly how the Continental growers produce their roots; but it has occurred to me that we ought to be able to produce equally good ones at home, seeing that we have to deal with a plant which is a native of this country, and one which grows and flowers freely almost anywhere out-of-doors. I am aware that home-grown roots have long been forced in gardens, the roots being generally selected from an outdoor bed, and packed together thickly in a pot, and forced immediately; but the flowers produced by such plants cannot be compared, either in quantity or quality, with those produced by imported roots, which appear to be grown under generous treatment, for when they come over here they have buds, as regards size, almost like *Asparagus* tops, and compact and firm bulbs. They are also of a suitable size for going into 6-in. or 7-in. pots, which they quite fill with beautiful foliage and pretty flowers. I have bought a quantity of imported roots annually for some years, and have always forced the same plants two years in succession and planted them out the third year about the borders, and, having in this way got a little stock, I mean in future to try if I cannot produce plants for forcing equal to those that are imported. Roots planted out produce abundance of flowers in our somewhat heavy soil, and under higher culture in pots they will no doubt do even better, and probably they will force a little earlier and more freely than roots that have been shaken out, as foreign ones are, to reduce the cost of carriage. Our plan is to lift the straggling runners which have pushed from the original stool just when peeping through the soil, or even when they have pushed some inches out before the leaves unfold. These have all good roots at the base, and they are packed as thickly as possible in 6-in. pots among good rich soil, potting moderately firm, and taking care to drain well. Afterwards they are set out on the ground as closely together as they will stand, to keep each other cool and moist, the outside of the pots being surrounded with rotten litter, and the plants watered and cared for just like *Strawberry* plants for forcing. It is not yet too late to lift and pot, and at the same time put out two-year-old pot plants to keep up stock; but it is as a forced plant that the Lily of the Valley is most appreciated. Its flowers are then well developed, the spikes long, and the foliage fresher and greener-looking than ever it is in the open border, where the flower-spikes are dumpy, and the flowers smaller. Though my own plants are growing in pots for convenience, the roots could, in all probability, be grown equally well in beds for the same purpose, lifting them about October or November, and putting them into pots as some people do their *Violets* and *Strawberries* for forcing. Although it is said to be a shade-loving plant, I find it to thrive amazingly on a sunny south border, among other herbaceous plants. In bed culture, therefore, I would recommend a similar situation as being the best for securing well-matured buds. Take the roots up, the same as for potting, and plant them in bundles about 9 in. or 12 in. asunder, packing the soil firmly between the plants, and seeing that it is previously

well enriched with rotten hot-bed or other manure. The point is to have the greatest number of flowering buds in little bulk, for the plant looks best in moderate-sized pots. The bundles for planting should therefore consist of single roots gathered up like a bundle of *Asparagus* in the hand, and thus planted, and during the summer the runners should be cut off with the spade, so as to keep each stool intact, and in autumn they will lift in proper form. The Lily of the Valley delights in copious waterings during the summer, and in the case of pot plants this must not be forgotten. Occasional waterings with weak liquid manure will also be found to improve the foliage and enlarge the future flowering buds. The difficulty of getting this Lily into flower early by forcing is well known, as it will not stand much pushing, and the Mushroom-house system of forcing is but a poor makeshift. I find the best way is to introduce the plants to the Cineraria-house as soon as potted in autumn—or a common greenhouse would do. Here they begin to move away very gradually, and by Christmas, or shortly afterwards, they begin to show their flowers in advance of the leaves, as they should do, and they then stand pushing in a warmer temperature without danger; but to attempt this sooner is perfectly useless. CHEF.

GROUND ORCHIDS—GREENHOUSE AND HARDY.

THERE are many representatives of this class in cultivation, but although some of the varieties are grown to perfection by a few, the majority of cultivators do not succeed with them, chiefly from inattention to the habits of the plants, and consequently they are not often met with; but when their culture is better known, we may expect to see them occupy that place in our gardens to which their beauty so thoroughly entitles them; the varieties at present imported from the Cape, &c., will soon be, let us hope, better understood and successfully managed, and thus new interest in this highly attractive class of plants will be awakened. The dread enemies to the greenhouse Orchids are heat and drought, and the same prejudices with which one had to contend in the case of the *New Granada Odontoglossum*, have now to be overcome with respect to the *Disas*, *Satyrums*, &c.; but, with the example before us of those cultivators who have brought them to such perfection with cold treatment, let endeavours be made to be more successful in their future treatment.

Disa grandiflora is certainly the most beautiful and showy of the greenhouse terrestrial Orchids, and well deserves its common name of the Pride of Table Mountain. It is found on that mountain in South Africa, on the margins of streams and pools, and during the growing season it flourishes in very wet, spongy soil, or partially submerged: as the dry season progresses the water gradually recedes, until, at the flowering time, the soil is not so wet; and shortly after they have ceased blooming the water disappears and the plants are left comparatively dry until the wet season again comes round. The dry season is the period of rest, but even during that time the plants are not without moisture at the roots, the soil in which they grow being sufficiently damp to preserve them in vigour until the growing and wet season arrives. This, then, is the principal treatment that must be imitated as nearly as possible to ensure successful results in the rearing of these beautiful Orchids, and for the rest we must be guided by experience. The native soil, even, from which the roots are dug cannot be thoroughly relied upon as a guide, for they have been found growing in sandy loam, in sand, but more frequently in sandy peat. The time of flowering in its native habitat also differs from that in which it flowers under cultivation in this country, for, according to those botanists who have seen it there, it blooms in February, but with us it generally flowers in June, July, or August; therefore the mode of treatment should be that prompted by our knowledge of the plant in its native wilds, but so arranged as to co-operate with our seasons. The following has been found a successful plan for cultivating the *Disa grandiflora*:—At the present time the plants should be in full growth, and placed in the coolest and shadiest part of the greenhouse as close to the glass as possible, being freely supplied with rain-water; the underneath part of the leaves should be frequently syringed in order to

keep off the red spider and thrips, and the plants should be surrounded with moisture in every possible way until they show flower, which will probably be at the times previously stated; after the buds are prominent the syringing should be discontinued or confined to the lower leaves, but the plants should still be freely supplied with water until they have discontinued blooming, after which they should be removed to a cold shady pit for a time, and then be placed in the open air in the shade, having their pots plunged in Sphagnum Moss. This being their resting season they should be more sparingly watered, but should not be allowed to get perfectly dry, and the Moss around them should be well watered. On the approach of bad weather, the plants should be replaced in the cold pit; they begin to grow again in October or November, when they should be removed to a cool place close to the glass in the greenhouse, and kept moist, but not too wet, until February, at which time they should be turned out of the pots, removing what is possible of the old soil without injuring the very brittle rhizomes; the plants should then be placed in pans, crocked nearly one-third of the way up, keeping the crowns a little above the rims of the pans, filling in carefully with the compost in use, and top-dressing with living Sphagnum Moss. Continually moisten them with a fine-rosed pot or syringe, until they show signs of a vigorous growth, during which time too much water cannot well be given them, discontinuing the supply when the colours of their flowers are again visible. The Disas thrive best in pans in a mixture of two-thirds peat broken into small lumps (not necessarily free from sand), and one-third Sphagnum Moss and soft sandstone broken into pieces about the size of Filberts. If there be no sand in the peat, a little should be added. The plants should be placed in Denning's Pot-saucers (figured at p. 403), which I consider a great acquisition for this purpose, also for Masdevallias, Filmy Ferns, &c.; they will then have the air uniformly moist around them, which they cannot well receive in any other way, and will be, to a great extent, protected from the attacks of insects. Some of the best specimens of Disas ever seen have been grown in cold pits, but, knowing that plants so grown are often neglected, I recommend the greenhouse during the growing season of these Orchids, as they are more likely to be looked after there; nevertheless, anyone desirous of cultivating these plants and not having a greenhouse, must understand that they can be grown quite as successfully in a pit if carefully tended. The varieties of *Disa grandiflora* vary slightly in colour, but are generally of a crimson-tinted scarlet, the dorsal sepal, which is shaped like a labellum, being lighter; they are borne from two to six on a spike of from 1 ft. to 1½ ft. in height, each flower measuring about 3 in. in diameter. *D. spatulata* is a smaller-growing variety with pale blue flowers, with a curious, long, trowel-shaped lip. *D. cornuta* is a beautiful variety, partaking more of the habit of the *Satyrinum*, to which genus it is sometimes referred; it bears from twelve to eighteen flowers on a spike, and the beautifully-contrasted blue, white, pale green, and purple of the flowers form a splendid contrast with the bright green of the leaves and the paler green barred with brown of the stems. *D. lacera* and *D. macrantha* are pretty white-flowering varieties, the last-named, in addition to having flowers of a good size, is very sweet-scented. *D. ferruginea* is a curious variety, with brownish or bronzy flowers, and well worthy of cultivation. *D. longicornis* is a very beautiful and curious variety, with blue flowers; it is easier to cultivate than most of the other varieties. *D. Herschelli* is a very fine variety, with large blue flowers; it is the best of its class and easy to grow.

The *Satyrinums* are not so difficult to manage as the Disas, but there are only a few of them in cultivation; they are chiefly natives of South Africa and Abyssinia. Lovers of these plants will, no doubt, be glad to be informed that an importation of them and several fine varieties of Disa has been recently received by Messrs. E. G. Henderson & Son, of St. John's Wood. The *Satyrinums* have tuberous roots, and most of them have large, fleshy, bright green leaves, which spread themselves over the tops of the pots; the flowers, which last a long time in perfection, are borne on spikes about 9 in. to 12 in. in length, rising from the centre of the leaves. *S. aureum* is orange; *S. carneum*, light pink; *S. erectum*,

yellow; *S. cinnamomeum*, yellow and brown; *S. candidum*, white; *S. cucullatum*, green and brown; *S. albidum*, whitish. They thrive best in a mixture of one-half peat, and the other half turfy loam and sand, and may be grown in a cold pit all the year round; but it is better to place them in the greenhouse near the glass during the growing and flowering season; after that they should be removed to the cold pit, where they will soon lose their leaves, after which they should be kept perfectly dry until they begin to grow again, when they should be potted and watered freely.

The varieties of *Habenaria* and *Bonatea* will also be found well worth growing in pots, the latter having generally greenish-white flowers with a divided labellum and narrow sepals and petals, which give the flowers the appearance of being cut into shreds. *Bonatea speciosa* is one of the best; they require to be grown like the *Satyrinums*.

Orchis foliosa, a lovely variety from Madeira, has bright green leaves, and its purple flowers, like our *Orchis maculata*, are borne on spikes about 18 in. in height; it blooms in June, and, when grown in large pots, forms a splendid exhibition plant. It should be placed in the greenhouse during the growing season, receiving a liberal supply of water, and, after flowering, should be removed to the cold pit or to some shady place out-of-doors to rest; give water from time to time, for this, in common with other *Orchises*, has tuberous roots, which are renewed annually, and, if the plants be allowed to get too dry, the new roots will not be strong enough to make flowering growth for the next year; it thrives best in strong soil, the best compost being two-thirds turfy loam and one-third peat and silver sand.

Orchis maculata, and most of the other European varieties, are pretty objects when cultivated in pots, and should be placed in a cold shady pit, only removing them to the greenhouse when their flowers begin to show colour; after they have ceased flowering remove them to some suitable shady place in the open garden, where their pots should be plunged in Sphagnum Moss to prevent the effects of the variations of temperature on their roots.

The North American, Canadian, and European *Cypripediums*, when properly cultivated, rival in beauty the warm house kinds, to which those who have seen them at our floral exhibitions can testify. They are found growing in marshy places, and are of easy culture provided they be kept as cool as possible and supplied with plenty of water from the time they start into growth until they have finished blooming, which varies from May to July, according to the treatment to which they have been subjected; after flowering do not let them be so freely watered. The chief cause of failure with these plants is too much heat, which induces them to push forward at improper times, making weak growth, which prematurely dies down, and the plants are either lost or only grow again so weakly as to render them of little use. The whole of the greenhouse terrestrial, and hardy Orchids in pots should be so cultivated that the growing, flowering, and resting take place at a given time each year, according to the nature of each variety, so that the whole shall be completed in a year—not growing the plants too rapidly, which will necessitate a long and dangerous rest. The *Cypripediums* succeed well in one-third peat, one-third turfy loam, and the rest leaf-mould and sand. *C. spectabile* is one of the finest; it is a native of North America, and grows about 12 in. or 18 in. in height, bearing large, dark rose and white flowers. *C. spectabile album* is a white variety of the preceding. *C. acule* is a pretty dwarf variety, with large rose and purple flowers; this, also, is North American. *C. Calceolus* is a pretty variety, often found growing wild in this country; it has bright yellow and brown flowers. *C. pubescens* is a North American kind, resembling *C. Calceolus*, but stronger-growing; *C. parviflorum* is another of the same class. *C. macranthum* is a fine variety, with large purple flowers; it grows about 10 in. in height, and is a native of Siberia. *C. guttatum* is a Canadian variety, of dwarf habit. *C. japonicum* is a curious specimen from Japan, with greenish flowers of a good size, which are borne on a spike coming from between a pair of broad wing-like leaves.

Goodyera pubescens is a dwarf-growing North American Orchid, with leaves beautifully traced with silver on dark green; it rivals in beauty the hothouse kinds of *Anæctochilus*,

which it resembles; it is easy of culture. All the Cypridiums enumerated, the Goodyera, and most of the European Orchids and Ophrys, together with the Platantheras, &c., from the northern half of North America, may be cultivated in the open garden, in company with our own British Orchises, if proper care be taken to supply them with the soils as recommended above, keeping them copiously watered during their season of growth, and free from insects at all times. The proper place for all these plants when grown in the open air is the rockery or ferny dell, where they would be shaded by trees. Places for the plants should be selected chiefly on the shady side of the rockery, provided it be not too much shaded by trees, and suitable soil put into the nooks intended to receive them; they should be planted in clumps, and if carefully tended, will thrive well.

When these plants are cultivated in this way they acquire a freshness and vigour wholly unattainable in the open borders in which they are at present mostly attempted to be cultivated, a state of existence quite contrary to the nature of the plants. Nothing is more painful than to see these plants in rows, the different species being placed side by side merely to make up a border of hardy Orchids; under such circumstances if by chance a few struggle into flower, the effect of their beauty is wholly marred by the miserable appearance of their less vigorous allies. The cultivator should bear in mind that it is not cold which kills these plants, but drought—the cutting, dry, east winds, and the burning sun. Wherever Orchids are planted in exposed situations, they should be covered with a few dry leaves during the winter as a protection.

JAMES O'BRIEN.

Finely-flowered Dendrobium Falconeri.—I send you a flower or two of this Dendrobe, which I imagine must be a good variety, but I have only seen one other plant in bloom, the flowers of which were vastly inferior in size and brilliancy of colour to mine. My plant, a comparatively small one, has borne about ninety flowers this year. I must say that I think with its graceful, pendent, knotted, pseudo-bulbs, and its lovely flowers, Falconeri is a difficult Orchid to beat, and I am quite sure that among Dendrobiums it is *facile princeps*. I may add that my gardener, Mr. Hill, got a certificate from the Botanic Society, Regent's Park, two years ago for this same plant, but then it had only fifty flowers on it; this year it has nearly double the number.—W. MARRIOTT, *Down House, Blandford.*

Culture of Primula sinensis for Seed.—Sow early in March, pot off into thumb pots when the young plants are fit to handle, and shift them again into 5-in. pots, using a light compost of peat, loam, sand, and a little rotten manure. Grow them in a cool frame during the summer, and shade from bright sunshine. House them in September, keep them near the light, and never subject them to damp in winter, or to a temperature under 45° or above 50°. Keep them uniformly moist at the root, but not wet; and at all times see that the drainage is in good order, otherwise they will go off at the neck. Do not let them flower till April; and at this time, if they can have a position on an airy shelf close to the glass, it will be a great advantage. Under favourable circumstances the flowers will set without assistance, but it is better to fertilise artificially. With this object in view insert a small camel's-hair brush into the tube of the flower until it reaches the pollen, and in drawing it out just touch the stigma with it, and go over all the flowers which are ready in the same way. I ought to have stated that the plants which have the largest, most perfect, and finest-looking flowers generally, should be selected for seed-bearers. When the seeds are ripe, gather and dry them in the usual way.—CHER.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Genera elongata.—This old-fashioned Genera is still one of the most useful of the whole genus, continuing as it does to flower nearly all the year round. It grows to a considerable height, and its long tubular flowers, which hang in deep reddish carmine bunches like the leaves, are covered with down. It is a plant which requires but little care; in short, so long as it has plenty of warmth and water, it will continue to flower well all through the winter months.—G.

A New Stock for Eppiphylums.—A writer in the "Deutsche Garten-Zeitung," for March, recommends *Persicaria calandriniaefolia* as the best stock for Eppiphylums, and adds that the German florists in the neighbourhood of Düsseldorf have used it exclusively for several years. It is as easily propagated as *P. aculeata*, and makes a stronger growth; it is thus better able to support the heavy succulent growth of the Eppiphylums grafted upon it than *P. aculeata*. In short, this stock answers every purpose for which the *Cereus spectiosissimus* is used, and being more woody, it is not so liable to rot off if neglected.—B.

THE FLOWER GARDEN.

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

STILL the cold winds retard the coming of the flowers and spoil the beauty of those that have come. The long-neglected *Atragene austriaca* is one of the most beautiful plants of the week, resembling a Clematis, but with a distinct charm of its own. The white form is more attractive than what we should call the nominal or purplish one, and much more showy at a distance. It is a low climber, and is seen to greatest advantage trailing through low bushes, and also creeping over banks or rough rock-work. Both the purple and the white forms may be seen in good condition in Parker's nursery at Tooting. The effect of the Californian *Delphinium nudicaule* is very good now; it seems to be more at home in our climate than many plants from the genial coast on which it grows. It is particularly fine in Rumsey's nursery at Waltham Cross, where it is raised in quantity from seed. The florist's Tulips (varieties of *T. Gesneriana*) are opening, and as yet there is a good show of the early or what are called the bedding varieties. There is a superb display of these in the graveyard of the St. John's Wood Chapel, Wellington Road. The Poet's Narcissus—the form of it usually cultivated for the London market—is the finest hardy flower of the week, and more honoured than most hardy flowers by being grown in quantities, like a vegetable, in the London market gardens, as well as in the flower borders of all lovers of good hardy bulbs. A precious property belonging to the varieties of the Poet's Narcissus is their blooming in succession; the bloom of various forms is past before that of others opens. The showy flowers of the hybrid Pyrethrum and the Peonies are opening, while *Iris florentina* joins the many superb varieties of *I. germanica* now in blossom. The most beautiful native plant of the week is the Water Violet (*Hottonia palustris*), a water plant too seldom grown in gardens; with it is the Bog Bean, delicately fringed and chaste in hue. The Lily of the Valley, now forced so extensively that we cease to long for its appearance out-of-doors, opens leisurely its bells, and blossoms along with its companion in the Alpine copses—*Anemone alpina*. The *Camassia esculenta*, a blue-flowered bulbous plant, is also in bloom. Leichlin's *Chlorogalum*, a handsome, hardy, bulbous plant, with cream-coloured flowers, is in bloom at Kew, and the dwarf *Pentstemon nitidus* is also opening its earliest flowers. Some beautiful hardy Pea-flowers succeed those gone before, notably *Astragalus monspessulanus* and *Coronilla vagans*. The Geraniums and Poppies (*P. lateritium*) begin to show colour, and the American Cowslips (*Dodecatheon*) are among the most beautiful ornaments of the rock-garden or borders, though the east winds do much to prevent their perfect blossoming.

THE HERBACEOUS CORAL PLANT.

THE Brazilian Coral Plant is not rare in conservatories, and is often planted out in gardens, where its large clusters of crimson flowers make a brilliant show. This is *Erythrina Crista-galli*, and is generally sold by florists under that name or as the Coral Plant. It is easily managed by keeping its thick clumsy stem in a dry cellar in winter, and setting it out in the spring, as one would a Dahlia root. There are several other Erythrinas (the name being from the Greek word for red), one of which is found in this country from North Carolina southward. Probably every one recollects his first meeting with a striking plant, and though we have seen this many times since, its acquaintance was first made under peculiar surroundings. Twenty-five years ago this month the writer (in "American Agriculturist") was going down through the State of Sonora, Mexico, in charge of a government train. We travelled very smoothly until we came to what is known as Guadalupe Pass, where one could look down on a sea of mountain tops, and down which our waggons had to go. The descent was about 1000 ft., and for a good part of it the mules were taken out and the waggons let down by hand. Perhaps waggons have been taken down more difficult defiles, for it can hardly be called a road, but we have never seen it done. While all this hard work was going on, our eye caught sight of a large patch of the most brilliant scarlet at one side of our path and part way down the ravine, and there was

Alpine Wind-flower (*Anemone alpina*).

Gentian-like Speedwell (*Veronica gentianoides*).

Woodruff (*Asperula odorata*).

Yellow Asphodel (*Asphodelus luteus*).

Mountain Cornflower (*Centaurea montana*).

Large-flowered Chickweed (*Cerastium grandiflorum*).

Star of Bethlehem (*Ornithogalum umbellatum*).

Two-coloured Collinsia (*Collinsia bicolor*).

Gesner's Tulip (*Tulipa Gesneriana*).

Bog Bean (*Menyanthes trifoliata*).

Turfing Daisy (*Pyrethrum Tchihatchewi*).

Water Crowfoot (*Ranunculus aquatilis*).

never anything more tantalising; here below were plants we did not know, and above wore mules and their Mexican drivers, and waggons, that we knew only too well. At length the last waggon had been lowered, and the tempting plants could be visited without neglect of duty. Here was a sight than which we have rarely seen one more brilliant. A patch several feet across of what we knew to be a Coral Plant, but could hardly think it the same as that of the Atlantic and Gulf States, so far inland. Still it proved to be the same as that, which is *Erythrina herbacea*. It has a large thick root or underground stem, and two sorts of stems, 2 ft. to 4 ft. high, one bearing leaves only and the other only flowers, or with a very few leaves. The leaves are compound, having three divisions or leaflets, which are somewhat triangular egg-shaped, and sometimes lobed at the base; the stems and leaf-stalks are prickly. The flowering stems bear a raceme 1 ft. or 2 ft. long of narrow flowers which are about 2 in. long. The structure of the flower shows that the plant belongs to the Pea family, but here the conspicuous petal or standard, which in the Pea stands erect, is horizontal and folds over the other parts of the flower, and is of a deep and showy scarlet. The several-seeded pod is much constricted between the seeds, which are about the size of the common Bean, and of a bright scarlet. These brilliant seeds are often picked up by travellers in Florida and other Southern States, and they are frequently sent to us for a name. This Coral plant will probably prove hardy far north of its native localities, as the stems die down in the autumn, and the root is protected underground. Plants in our garden near New York survived the severe winter of 1874-75, and we trust that they may come out all right this spring. Should it prove, as now appears likely, hardy, it will be a valued addition to our borders.

SUB-TROPICAL PLANTS AND GEOMETRICAL GARDENS.

SINCE sub-tropical plants have become so plentiful in gardens as almost to equal, in numbers those that are grown for the beauty of their flowers, it becomes a question whether the form of our flower-beds should determine what should occupy them, or whether the beds should be altered to suit their occupants, seeing that upon the free, unfettered growth of sub-tropical plants much of their beauty depends. A geometrical garden, all points and angles, may look very well on paper, and even laid down in Box, but to fill it satisfactorily the plants must conform to pinching, pegging, and training, like a Verbena. Therefore the only fine-foliated plants available are those used for carpet bedding; but that these look best in elaborately designed beds I very much question, for it must be apparent to even those of limited experience in planting, that it is far easier to make an effective arrangement of the materials at disposal, in beds of simple design, such as circles, ovals, or squares, than it is to plant an intricate design so as to make it look well; for in the latter case the space is generally so contracted that little choice is left to the plants, whereas beds of simple design allow free scope for properly arranging and contrasting both flowering and fine-foliated plants. Beds on Grass and of considerable size suit fine-foliated plants best, as they are most effective in large masses, and the space between the beds should be correspondingly ample. It is a loss to purely geometrical gardens, which almost invariably occupy the most conspicuous positions of the highly-dressed grounds and the best views from the windows, that the forms of the beds of which they consist should so entirely exclude the majority of the finest varieties of sub-tropical plants, which are on that account forced to be accommodated in sequestered nooks and glades, where they attain full and free development. Before, therefore, deciding on any particular plan for a flower garden, it would be well to take care that, in addition to its looking satisfactorily on paper or on gravel with Box-edgings, it also answered the purpose for which it was intended—viz., to exhibit in the most effective manner consistent with our climate the most beautiful forms of vegetation from more favoured lands. When beds are divided by walks not wide enough to walk in, and the beds themselves, owing to their numerous points and angles, are only capable of being effectively filled with miniature plants, it becomes obvious that the pleasure of seeing the most favoured positions filled with the best plants is lost.—J. GROOM, *Henham*.

The Weirleigh Surprise Forget-me-not.—In a recent number of THE GARDEN mention is made (see p. 348) of a variety of the *Myosotis sylvatica*, under the name of Weirleigh Surprise, having been lately exhibited as a novelty. It is one in reality, but it has been growing in the Queen's County, in Ireland, for some years. I exhibited two large pots of it at the Horticultural Show in Dublin on

the 27th of April, grown from slips obtained last autumn, but no notice was taken of them in the reports. Its ground colour is white, with a distinct blue stripe in each division of the corolla, forming a very pretty star-like marking. It is rather remarkable that this variety should have sprung up in two localities so remote. The specimens exhibited here have more the character of *M. desiflora* than *M. sylvatica*.—J. WALSH, *Hollybrook, Foxrock, near Dublin*.

A FEW SPECIES OF TULIPS.

By far the best Tulip which I have seen for many a day is *Tulipa Greigi*. Mr. Fitch's beautiful figure of it in the Bot. Mag. for 1876 is no exaggeration; it simply does justice to this splendid species. For some weeks past its handsome brown-spotted leaves have been a conspicuous ornament to the garden, and they are now surmounted and set off by gorgeously bright orange-red flowers. Its short stalk and tidy growth, too, render it all the more desirable. It appears to be a very hardy and healthy species, and comes up freely from seed. I am also much pleased with the bright little *Tulipa Julia*, which M. Max Leichtlin tells me is a small form of the handsome *T. Eichleri*, of which Mr. Fitch also gave us a figure last year—it might well be called *T. Eichleri minor*; it is very dwarf in growth, and has bright scarlet-pointed petals, with a black and yellow centre. *Tulipa Hageri*, with the outside of the petals of various shades—of red sometimes tinged with green, and the inside red with a black centre—is also interesting. *T. maculata*, closely allied to *T. Julia*, but double the height, and in colour much resembling *T. oculis solis*, makes a very gay clump. *T. acuminata cornuta*, with its strange narrow parti-coloured petals, is so quaint and curious that no one who has once grown it likes to be without it. I am very fond of the rather too tall but graceful yellow and green *Tulip*, which comes to me under three appellations—*T. altaica*, *T. præcox*, and *T. viridiflora*; it harmonises well with its lovely congeners *T. elegans* and *T. retroflexa*, whose beautiful magenta and canary-yellow reflexed petals are a sight to gladden one's heart on a bright sunny morning. Can any of your readers tell me the origin of a very remarkable *Tulip* which is known in the trade under the name of *T. vitellina*? It has pointed, reddish-orange petals, with a conspicuous white median rib on the outside, and a black central eye. Mr. Baker, to whom I sent a flower, thinks it is either a garden race of *T. oculis solis*, or a hybrid between *T. acuminata* and *T. Gesneriana*. Many species of *Tulip* have this year no blooms. In consequence of the wet summer of 1875 the bulbs did not ripen properly. H. HARPUR CREWE.

Drayton Beauchamp Rectory, Tring.

Climbers on Dead Trees.—A few years ago one of our old Spruces (*Abies excelsa*) died. It occupied a conspicuous place in the front grounds. We cut off all the twigs and the ends of the main branches so as to form a cone, with the apex 15 ft. high, and the base about 8 ft. diameter. The extremities of the branches were connected from the bottom to the top with strong twine, forming an irregular network. Underneath the circumference of the base a trench was dug and filled in with good soil, then Climbers (*Cobæas*, *Lophospermums*, *Maurandias*, and *Madeira Vines*) were planted. They soon reached the top, and so covered the netting that the eye could not penetrate beneath its entangled surface; and the effect of this cone of leaves and trumpet flowers was one that caused many a passer-by to stop and admire what, at a first glance, seemed to be a tree bearing dissimilar flowers and foliage.—"Moore's Rural." [A no less desirable and more permanent effect may be easily obtained by planting choice free hardy Climbers, such as *Clematis grandiflora*, in like manner. In countries where there is an open winter, *Clematis balearica* is particularly suited for this purpose, as it flowers beautifully in winter and spring. It need hardly be said that the new *Clematises* may be grown in this way, but these are assured of careful culture and pleasant homes in our gardens. It is the many seldom seen and neglected small-flowered *Clematises* and other fine Climbers that are either never grown at all, or, if grown, mutilated against a wall, that ought to be grown in this happy manner. Whole gardens of beauty might be formed in many a place where there is not now a single Climber, by clothing dead trees and shrubs in this manner.]

The Iberian Iris (*I. iberica*).—I have this now in fine bloom, and, according to my idea, it is one of the best of all hardy flowers. Though often said to be a difficult plant to grow, I find it do well in a border of ordinary sandy loam. The flowers are simply magnificent, very much in the way of those of *I. salsiana*, but I think finer. *I. salsiana*, though it exists and occasionally flowers in a fulfil manner in the open border, requires either frame or hand-light pro-

fection to induce it to thrive, whereas *L. iberica* is quite independent of any sort of protection. When in full bloom it does not grow more than 1 ft. in height, and more resembles an Orchid from some sunny clime than a plant capable of withstanding the vicissitudes of our fickle climate.—OXON.

GARDEN VEGETATION DURING APRIL.

By JAMES M'NAB, Royal Botanical Garden, Edinburgh.

IN Scotland the month of April has been very variable, attended with much wind, snow, and rain, with the exception of one week at the beginning, when mild weather prevailed. On six consecutive mornings, viz, from the 4th till the 9th inclusive, the thermometer at 6 a.m. registered between 44° and 57°, the highest being on the morning of the 5th. During the month the thermometer was fourteen times at or below the freezing point, indicating collectively 69°, being considerably more than has been registered during the month of April for twenty-two years, as will be seen by the accompanying Table. This Table gives the number of degrees of frost registered during each month from October 1st, 1854, till April 30th, 1876. The lowest temperatures indicated during the month were on the mornings of the 2nd, 3rd, 11th, 13th, 17th, 23rd, and 30th, when

List of Conifers which have suffered.

<i>Thuja orientalis compacta</i>	<i>Thuja aurea</i>	<i>Juniperus chinensis</i>

25°, 27°, 26°, 20°, 27°, 25°, and 25° were respectively registered, while the highest morning temperatures were on the 4th, 5th, 6th, 7th, 8th, and 9th, when 45°, 57°, 50°, 60°, 44°, and 44° were indicated. The cold, backward, and changeable weather experienced during the greater portion of April has been very much against vegetation, many of the trees being still in their winter condition. The moisture, however, to which they were subjected towards the end of the month has swelled the buds considerably, and rapid progress may be expected during May. Such an excess of rain penetrating the ground before the leaves expand, generally brings a rich and full foliage, which is rarely the case when the leaves come out during very dry weather, unless in situations where the ground is naturally damp. Hardy spring flowers are also far behind, and many of them are much injured by the frost. After the mild weather during the beginning of April, which was followed by several frosty mornings, the lowest marking was on the 13th, when the thermometer indicated 12° of frost. This sudden change of temperature has injured many Coniferous shrubs, particularly those belonging to the *Cupressus* group; also a few species of *Juniperus* and *Pinus*. The injury to the *Cupressinae* section was probably hastened by the sudden change of colour which most of them assumed. A large proportion of the species injured are of Eastern origin, and a few are natives of the Western hemisphere. *Piceas* and *Abies* have all wintered well. The following is a list of the species which have suffered most—

The following spring plants complete the list of species annually recorded to show their periods of flowering:—

<i>Hyoscyamus physaloides</i>	1876.	1875.
<i>Narcissus pseudo-Narcissus</i>	April 2	March 31
<i>Adonis vernalis</i>	April 1
<i>Fritillaria imperialis</i>	March 29
		April 18

Select Varieties of Double Daisies.—Having last year purchased most of the sorts of Daisies enumerated by "A. D." (see p. 428) I am enabled to endorse nearly all the remarks made by him in respect to them; but, in addition, I purchased a 2s. 6d. packet of seed early in the autumn and sowed it at once, and nearly every seed must have grown, for I have been able to plant out probably not less than 1000 plants as edgings to paths, with a result this spring far exceeding my anticipation. Some of my seedlings are exceedingly good, and the variety among them very great. I observe that "A. D.," in speaking of *Pink Beauty*, describes it as being a close-qualified variety but showing the eye too much. I am not acquainted with that particular kind, but among my seedlings I can find a pink-qualified variety, without an eye and very globular; at present it is, however, small,

* This plant is flowering freely in the stove compartments, which is not the case in the open border.

not being larger than Bacchus, but I do not expect to find seedlings at their best the first season. Last year I bought both seedlings and named plants, and when the seedlings came into bloom I was somewhat disappointed, but, as my stock was then limited, I did not destroy them; on the contrary, I completed an edging with them, begun with such sorts as Queen Victoria, Nil Desperandum, Kenown, Mastopiece, &c., and, to my surprise, this year the seedlings turned out nearly as fine as the named varieties. I intend taking advantage of "A. D.'s" suggestion regarding the formation of a bed of Daisies, and hope in due course to report the result.—W. H., Luton.

Wild Austrian Pinks.—Perhaps some of your correspondents may be able to give replies to the following questions:—Are seeds or slips of the beautiful, single, rose-coloured Pink, which grows wild in profusion in the neighbourhood of Innsbruck, and also in some parts of Northern Italy and Germany on rocky banks, to be had in Britain? and if so, where? Some years ago I brought home seeds of these wild Pinks collected abroad; they grew freely in a garden in South Wales, seeded, and continued in the ground for several consecutive years, but at length were lost, it is believed, in consequence of neglect. These Pinks, of a pale rose hue, would not only be a useful addition to all gardens, but would probably flourish on the tops of walls as well as Wallflowers or Snapdragons.—L.L.

Raising Polyanthus from Seed.—I have been cultivating Polyanthus for some years past from seed, and have now a good collection of them. This year I could have out a bushel basketful of bloom at a time. I tried several times to raise them by sowing in boxes or pans under glass, but the young plants always came up weakly; I find it best to sow in the open ground, as seedlings raised in this way make stronger plants in less time, and incur less trouble. An open piece of ground in the kitchen garden, enriched with leaf-mould, suits them well; it is raked very fine; the seed is sown broadcast, and raked in. In hot, dry weather, the young plants require watering, or they lose their foliage, which tends to weaken them, and consequently the bloom will not be so fine as it otherwise would be. Thus situated I leave them to bloom, and as there are always some not worth growing these are pulled out at once and thrown away; others, of superior merit, are lifted for potting or for planting in other quarters; a small stick is placed to those from which I intend to save seed. I like to make two sowings—one as soon as the seed is ripe, and another early in spring. I have sometimes sown under partial shade from a tree, and thus circumstanced they do well, being protected a little from the hot sun and spring frosts. Both birds and slugs are very destructive to Polyanthus blooms.—W. DIVERS, *Wierton, Maidstone.*

Caltha palustris monstrosa.—In most collections of hardy plants the double variety of *Caltha palustris* may be seen, and a fine showy object it is at this season when covered with its brilliant yellow flowers. My object, however, in writing is to recommend a much finer variety known as *C. p. monstrosa*. The colour of the bloom is not of quite such a dark hue as that of the ordinary variety, but as the individual flowers and leaves are nearly double the size it is a still more desirable plant. It is generally seen in nurseries plunged under water in pots, but this is by no means necessary, as it does well in any border not too dry. Here it is in a border under a north wall, and gets no more water than other plants in the same bed.—OXON.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

New and Rare Trilliums.—Among spring flowers you strongly commend *Trillium grandiflorum*. It is a lovely plant, but there are two other species which I should also recommend to all who admire and can grow the Trilliums. One is *T. nivale*, of the purest white and dwarf; the other is *T. septentrionale*, with narrow pure white petals, showing the pale green sepal between and a rich purple ovary, making altogether a very beautiful combination.—H. N. BRACKENRIS, *Elfton Vicarage.*

The Umbrella Plant (*Saxifraga peltata*).—This is one of the best of Saxifragas; its stem, which are an inch in height, is a bush of from 12 in. to 15 in., and bear large terminal heads or clusters of bloom, of a bluish-pink in colour. The petals vary in number from five to eight, and the stamens from eight to fifteen. It is in flower now before the leaves appear, and is a fine plant for borders in front of shrubs.—R. H. B.

Christmas Roses Seeding.—Does the Christmas Rose bear seed? is a question often asked. This, I think, depends very much on the weather at the time when the plants are in bloom. I have a large clump of it on a sheltered border, with quite a load of seed-pods just ripening. I find that the old flowers remain intact until the pods are fully matured, and that they change from clear white to a dull green. The blossoms measure fully 4 in. across, but their size is greatly influenced by cultivation, as this same plant, when growing in a poor scrubby border, produced flowers quite small in size.—J. G.

Edgings in Shady Places.—M. Van Hulle recommends the old and graceful *Menyanthes trifoliata*, an umbelliferous plant occurring in most botanic gardens, as a good subject for forming edgings in shady places. He also praises common hardy Ferns for this purpose.

PLATE XXI.

THE JAPAN IRIS.

(IRIS KÆMPFERI VAR.)

THIS slender-growing evergreen hardy Iris, from Japan, often attains a height of 2 ft. For many of the most beautiful varieties of it now in cultivation we are indebted to Dr. von Siebold, the celebrated German botanist, at Leyden. Kæmpferi is but a garden name, its proper one being *Iris setosa* of Pallas, a name under which, however, it is scarcely known by cultivators. It is a plant which will grow in almost any kind of soil, but it succeeds best in a good loam, provided a quantity of peat be added to it, not so much to afford nourishment as to retain moisture during the summer months, for plants of this Iris like moisture, and their numerous roots will often go 2 ft. deep in search of it. It dislikes shade; on the contrary, it prefers a sunny, hot situation. Two-year-old seedling plants of it flower in June and July, and among them will be found endless variations of colour, from white to dark blue, and from pale rose and lilac to deep maroon and brown. Complaints are often heard that plants of these Irises are difficult to flower, and the fact is, that if not carefully transplanted, they do not flower the first year, but are on that account so much finer the second season. In short, they must be well established before they can produce fine flowers. They may be propagated by division and by means of seeds, which should be sown as soon as gathered, either in pots or in the open ground, when they will vegetate the following spring. Some beautiful varieties of an Iris bearing this name have been sent out by Messrs. E. G. Henderson & Sons, of the Wellington Nurseries, one of which has the larger outer petals doubled, that is, six instead of three. These seedlings are certainly very fine, but they do not belong to the Kæmpferi or *Setosa* race; they are garden forms of *Iris lævigata* of Fischer. All of them are well worth cultivation, and it is to be hoped that repeated trials in raising seedlings will result in getting them to bloom more freely than at present. MAX LEIGHTON.

Borage and some other Common Plants in the Garden.

—The increasing interest of THE GARDEN to the majority of lovers of flowers who are not and never will be botanists or interpreters of floral Latin encourages one of the above class to make a few suggestions, as well as to ask a few questions, hoping that if a reply be given the names of flowers may be as intelligible as in the delightful reports regularly given of hardy flowers blooming in the week. Is not Borage (as it is sometimes termed) too much neglected? It is one of the most beautiful of our blue flowers, which are so much rarer than other colours. The wild Blue Veronica or Speedwell would be a grand addition to our gardens if it would bear cultivation, and it is to be hoped that the readers of THE GARDEN are now so enlightened as to the beauty and value of all wild flowers that no one will be alarmed at the suggestion of bringing the Dandelion into cultivation as an ornamental flower, the beauty and brilliancy of which at this present time make me daily regret that I had not transplanted some last year. A friend having sent me a turf out of the Swiss pasture, which appeared to contain several wild plants, I planted it on a raised bed. The first two years plants of the wild Blue *Salvia* flourished among the Grass, but these have now disappeared, and 't seems probable that the great increase of a gigantic species of Dandelion and also of a Thistle, which is not the same as the Common Thistle, although it resembles it, has overpowered the Blue *Salvia*, which thrives in various parts of Germany where the climate is intensely cold in winter, and especially in the neighbourhood of Munich. The Yellow *Salvia* grows wild in great luxuriance, and in profusion about Lugano, where the Yellow Foxglove is also found wild. Among the innumerable garden flowers which seem to have become almost extinct from the pernicious system of depending solely upon bedding is the Scarlet *Lobelia*. The white hardy Jessamine and the old-fashioned Honeysuckles, viz., the fragrant White which blossoms in May, and the fragrant Red and Yellow, which used to be an indispensable accompaniment to a nosegay of Roses, are now very seldom seen; indeed, Honeysuckles and Periwinkles are deserving of much more attention; the large flowering blue kind of the latter is certainly well called for its evergreen foliage, great adaptability, and numerous and beautiful flowers for so large a part of the year. Would it be too much to hope that THE GARDEN may gratify its readers by giving a weekly or monthly list of wild flowers, which would afford additional beauty to our gardens?—Z.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Ferns.—Some have thought it necessary to have a house wholly devoted to Ferns, where anything approaching successful culture is required, but such is by no means the case; certainly where they are to be grown in a way that will exemplify the true character of any of the kinds, a somewhat close humid atmosphere is necessary; the fronds will also assume a deeper tint of green under such conditions, accompanied by close shading, but this system of management is not calculated to impart the more sturdy state of growth particularly needful where the fronds are wanted in a cut state. Amateurs, who have an ordinary greenhouse or Vinery need have no hesitation in attempting to grow them in such houses, particularly if a selection of the most suitable sorts be made; but when associated with other plants, instead of having them interspersed amongst those that are altogether different in their requirements from Ferns, it is better to place them together at one end of the house. If an ordinary stage occupy the centre, the Ferns will do best placed at the darkest side, which is that which is least suited to flowering subjects; if Vines or climbing blooming plants be grown up to the roof, these will afford the requisite shade; if not, a piece of thin material may be hung over them inside the glass, so as not to prevent the other occupants from getting all the light which they require. In all cases it is best to keep Ferns that are intended for cutting under-potted, after they have arrived at a size large enough to produce fronds in sufficient quantities. The air and light which flowering plants need will be found to induce a harder condition in the case of the Ferns, and will render them better suited to the purpose required. *Adiantum cuneatum*, which is a general favourite, will grow to a fair size in houses such as those under consideration. The stronger-growing *A. formosum* will stand better in a cut state even than *A. cuneatum*; *A. Capillus-Veneris* will also succeed very well under such treatment, as will likewise *Pteris serrulata*, both the normal and crested forms that now exist, all of which are of a hardy character. The white and green variegated *P. cretica albo-lineata* is also suitable for growing in this way. *Davallia canariensis* and *D. bulata*, *Doodia aspera* and *D. lunulata*, are all appropriate, both in size and habit, for the kind of management suggested. One of the most useful Ferns in cultivation is *Lomaria gibba*, when it is not allowed too much root-room. If any be needed for the decoration of sitting-rooms, for which the more hardy kinds of Ferns are very suitable, they should be properly prepared for that purpose by not being previously grown too tender. Many Ferns are kept confined in cases shut up with very little air, that would do quite as well in a room without any covering if they were not subjected to the influence of gas or too much dust. Where plants are required for room windows facing the north, Ferns will be found to succeed best. Amongst the most suitable kinds for room decoration are the numerous forms of *Scelopendrium* and *Asplenium marianum*. Many other Ferns, in addition to those named above, may be grown in such places as greenhouses and Vineries, but those named are more particularly adapted for general decorative purposes, and especially for cutting. One of the principal points in their cultivation is never to allow insects to get established upon them, which they inevitably will, if means be not taken for their destruction as soon as they make their appearance. This remark especially applies to thrips, which may be expected to attack them every summer. For these, dipping in Tobacco-water is the best remedy; brown scale is even worse than thrips, for although it does not increase so fast, still, from the inability of many Ferns to bear dressing with any insecticide that will kill the scale, it entails a great deal of labour to keep it in check by means of hand-cleaning. In the selection of plants, particular care should be taken to see that they are free from it, and never to allow them to touch each other, or to remain under any infested plants, for in either case they are sure to get affected. Ferns grow most freely in peat, but good fibrous loam gives more substance to the fronds; in both cases one-sixth of charcoal broken in bits about the size of Horse Beans, and mixed with the soil, in addition to a sprinkling of sand, will be found beneficial; if charcoal cannot be had, coal cinders will answer the purpose. See that the pots are well-drained; $\frac{1}{2}$ in. in the bottom of a 6-in. pot will not be too much, and more in proportion to the size of the pots, in all cases putting half an inch of Sphagnum, or fibrous pieces of the potting soil over the drainage, as the quantity of water required by Ferns when in active growth is such as to render this necessary, in order to keep the soil from being washed down into the drainage, and thus preventing its acting properly. With Ferns, as with other plants that need protection from the direct rays of the sun, the shading used should not be left over them when not required, for although they will not have quite such a dark green appearance when subjected to a great deal of light, they will be found much better calculated to fulfil the purposes for which they

are wanted. Those who have not had any experience in Fern culture need not doubt succeeding, provided the above directions be followed; in addition to which they must never be permitted to get dry at the roots, or allowed to flag from want of water.

Pelargoniums, both fancy and large-flowering kinds, will now require more water than they did in winter; if they have made satisfactory progress through the spring, the soil will be completely filled with roots, and if, in this state, they are ever allowed to become so dry as to cause the leaves to flag, all those about the base of the plant will be liable to turn yellow and drop off. With Pelargoniums such as those just mentioned, amateurs who have not had much experience in their cultivation will find it safe practice to keep the soil all through the winter in a much drier state than would do for the generality of other plants; but, if treated similarly at this season, they will not succeed. They require very different treatment from the Zonal section in the matter of water, and through a want of knowledge regarding this many do not succeed in growing the large-flowered and fancy kinds, often confining their practice to Zonal kinds alone, which do not possess nearly the beauty or variety of the former. If any traces of aphides be found on them, let them be fumigated twice in succession before they come into flower, as, if this has to be done when the plants are in bloom, it will cause all the flowers that are open to fall off. It is a good plan to fumigate Calceolarias once or twice slightly before the flowers are too far advanced, or the effects of smoking will cause them to come deformed.

Cyclamens that have done blooming should be put in frames, where they will be partially shaded from the full force of the sun; keep them moderately moist at the roots and quite free from aphides and red spider, for, if either of these insects be allowed to get possession of the plants, they will quickly injure the leaves to an extent that will seriously interfere with their flowering during the forthcoming winter. Give them sufficient air, but not so as to dry the atmosphere around them too much. Failure in the cultivation of Cyclamens may often be traced directly to exposing them in full sunshine in the open air, to loss of leaves through insects, and to keeping the roots too dry, with insufficient warmth in winter. Young bulbs raised from seeds sown last autumn should be well attended to, keeping them moderately close and moist, with plenty of light, but not too much sun; be careful never to over-pot these plants, 3-inch or 4-inch pots for the autumn-sown bulbs will, until further in the season, be large enough. They will do well in a compost consisting of three parts turfy loam to two of leaf-mould, with a good sprinkling of sand.

Spiræa (Hoteia) japonica.—Plants of this that have been forced or brought into flower in a greenhouse are often, when done blooming, set in any out-of-the-way corner and little attended to in the way of moisture, whereas, if properly treated, they would go on increasing year after year. By some they are turned out of their pots and planted in the open ground for the summer; in autumn the roots are taken up, divided, and again potted for forcing. This treatment is right so far as the planting-out goes, but, instead of deferring the division of the roots until the time when they are being potted, the division should take place now, when they are planted out; obviously in this way the roots will receive less check at a time when their flowering is more likely to be interfered with through it than now, before they make growth in the open air, and have all the summer to recover its effects. The soil in which they are planted should be moderately light and rich, and they must never be allowed to suffer from want of water.

Balsam and Globe Amaranthus.—Seeds sown now will come into flower late in the summer when there is a comparative scarcity of greenhouse-blooming plants; they will succeed very well in cold frames after this time; but, if in a hot-bed that happens to be at work, the seeds will germinate more quickly. As soon as the plants are up and 2 in. high, put them singly in small pots, using rich soil—ordinary loam, three parts to two of leaf-mould and rotten manure in equal proportions, with some sand, will suit them perfectly.

Stoves.

The weather of late has been most trying to plant cultivators, for, during the early part of the month, strong winds were blowing from the north as cold and cutting as at any time during March; this, accompanied with clear sunny days, rendered much care necessary in giving air to keep down the temperature in the stove houses. It is not likely at this late season that we shall get a recurrence of such bad weather, but when cold winds prevail it is always better to allow the thermometer to run up considerably than to risk letting in air to come in contact with the young tender foliage that stove plants are now making. If the shades be kept down at such times, and

plenty of moisture in the atmosphere maintained by frequently damping the floors, pathways, &c., a rise in the temperature to 90° or so may be allowed with advantage, and will be found far more congenial to the health of the plants than admitting a rush of cold air. With all the care that can be exercised in this way, it is surprising how rapidly plants dry under the influence of such weather, and much watchfulness is therefore requisite in keeping them properly supplied with water at the roots.

Achimenes.—Many of the quickly growing stove plants, such as Achimenes, Gloxinias, and others of that class that have filled their pots, and are getting well forward for flowering, can scarcely be kept too wet if potted in loose, peaty soil with plenty of drainage. Under such conditions, with the proper amount of heat and abundance of moisture in the air, they will keep their colour and produce a quantity of large flowers, without which Achimenes have but a poor weedy appearance. In affording these the necessary shade, they are frequently kept too far from the glass, thus having an insufficiency of light, whereby they become drawn and are then of little value for decorative purposes. To secure a successful growth they should be placed in light airy positions where shade can be afforded them for a few hours during the hottest part of the day while the ventilators are open, after which, with a good syringing, it may at once be withdrawn from them, as they will stand a fair amount of sun when closed with a moist atmosphere surrounding them. Achimenes thrive well in pits or frames at this season, provided they can get a little artificial heat, such as by having a bed of gently-fermenting leaves or tan under them, the genial heat and moisture arising from which exactly suit their requirements. With the limited body of air such places afford it requires great watchfulness to keep their leaves from burning, and to prevent this it is necessary to have the shades on betimes in the morning before the sun's rays are too powerful upon them. Those that are sufficiently advanced to require support should be neatly staked and tied, giving the outer sticks a sharp inclination, that the plants may be spread out and have plenty of room for the lateral branches to grow without being crowded and drawn. Fine Privet twigs that were trimmed off during the summer and tied up in close bundles to dry make the neatest and best stakes for training and supporting Achimenes, as they are but little larger than the stems of the plants, and being of the same colour from retaining their bark, they are scarcely noticeable. Deal sticks or others made by hand, unless painted or coloured, are very objectionable, independent of the time and labour they take in getting them prepared, and therefore a stock of the above, as well as Hazel and Willow for training Pelargoniums and such like plants, should always be kept ready for use.

Gloxinias.—These require similar treatment to Achimenes as regards heat, light, and moisture, and when well grown, are among the most useful of summer-flowering plants. By keeping them well up to the glass, the blooms are much improved in substance, and consequently last a greater length of time on the plants or in a cut state than they otherwise would. Any seedlings that are up and sufficiently large to handle should at once be pricked off in peaty soil in well-drained pots or pans, and then placed in close, moist heat to give them a start. A sheet of glass laid over them and slightly tilted will be found of great service in helping them to get hold of the soil, which they will soon accomplish if kept gently syringed as occasion requires. By pushing these on for the next month or two, they may be had in bloom by the autumn, and will come in most useful to succeed old plants then going to rest. Where it is desired to increase the stock of any fine kinds, one or two of the lower leaves should be taken off as soon as of sufficient size and tolerably firm to be used for propagating purposes. They may either be put in whole or cut across the middle, but the former is the safest and best as being least likely to damp off through not having any cut part exposed to the air, or on which moisture can lodge. The leaves should be taken off with a short piece of the foot-stalk attached, and then inserted in small single pots in sandy soil. If then placed in a propagating box, or under bell-glasses, in moist heat, they will soon callus, and will begin to form tubers that will make fine flowering plants for next season.

Celosias.—The great improvement that has been effected in these of late renders them very acceptable plants, either for supplying cut flowers or for furnishing conservatories and greenhouses during the autumn. Good strains of them make most elegant pyramidal-shaped plants clothed with long, pendulous, brilliant-coloured inflorescence at the end of every shoot, and almost at every joint. These have, when well grown, a light, feathery appearance, and produce a striking effect, especially when seen under artificial light; they are, therefore, most valuable for dinner-table decoration, as small plants in vases or in a cut state for dressing epergnes, in which position they droop gracefully over the side and show up in pleasing contrast with the white damask cloth and other surroundings.

Where showy plants are in request for furnishing purposes, such useful subjects as these should not be lost sight of, as they may be grown up quickly and at once discarded when they become the least shabby; but with ordinary care and suitable places in which to arrange them, they may be kept in fresh condition for at least three months. If seed be sown at once and the plants grown freely on when up, they may attain a large size by the middle or end of August, a time when gay flowering plants are generally becoming scarce. Celosias are rather subject to red spider, and to keep them clear of this pest they must be frequently syringed and never allowed to suffer for want of pot room or a proper supply of water at the roots. Owing to their rapid growth in a warm, moist atmosphere the plants draw up weakly and long-jointed, in which condition they are unable to bear the weight of their flowers without support, and when stakes have to be resorted to, it detracts much from their beauty. To avoid this they should be kept well up to the light and placed at a sufficient distance apart to allow proper room for sun and air to play freely amongst them. A common pit or frame having sufficient depth to hold a few leaves or other gently fermenting material in which to plunge them will be found more suitable than the stove, as, in the former position, they are more under command, and can be syringed and treated more in accordance with their requirements than when grown among other plants.

Cockscombs.—These, though not so graceful as Celosias, make a fine display when well managed, and, if sown now and similarly treated, will make fine, showy heads by the autumn, when they are sure to be acceptable for furnishing purposes. Both these and Celosias are gross feeders, and should have rich soils in which to grow. A fourth part of good, sweet, rotten manure to three parts of loam will be found to suit them well. Such masses of flower, in proportion to the size of the plants and the amount of foliage they carry, necessarily make large demands on the roots, and to meet this and keep them of a healthy, green colour, they should be assisted by a liberal supply of manure-water as soon as they begin to show bloom. If either be required for seed-saving purposes, they must be kept well apart, or both will be spoiled, so freely do they intermix and cross with each other.

Balsams, like most other free-seeding plants, have of late been considerably improved, and instead of the weedy, single-flowered subjects once grown, they may now be had almost as large and showy-looking as moderate-sized Camellias. To have them in perfection, they can scarcely be overfed, and should be grown in soil containing nearly half its bulk of manure, provided the latter be of a mild nature, such as can generally be obtained from old hot-beds that have been frequently stirred. If desired of large size, they must be kept shifted on, so as to hasten their growth as rapidly as possible, and until they are placed in their flowering-pots, the blooms should be picked off as they continue to show themselves. At each shift they receive the plants may be dropped lower in the soil, that the bottom branches may be pegged or tied down, so as to be level with the rim of the pot. To keep them short-jointed and stocky, they must be well up to the glass, and fully exposed to the sun, giving them plenty of air whenever the weather is favourable. No place in which to grow these surpasses a low house or pit, where they can receive a slight bottom-heat, in which, if syringed and shut up early, their growth will be most rapid. As soon as the pots are filled with roots, manure-water will be of the greatest assistance in developing their blooms and pushing out plenty of lateral shoots that will continue flowering after those on the main stems are over.—J. SHEPPARD, *Woolverstone Park.*

Orchids.

Any Orchids coming into flower should be removed to the cooler end of the house as soon as the first flowers expand, and left there until they are all open; they will be then prepared for removal into a cooler house while they are in flower without receiving any check. Take care that the flowers do not get wet, or they will be spotted, and will not continue in bloom nearly so long. This treatment of plants in flower is particularly useful if they be intended for exhibition or for the decoration of the dwelling-house, where they will last in beauty and without injury for a much longer period than if they had been left in a warm, damp house. Care should be taken that when in flower the plants should be placed where the sun's rays or the heat from the pipes do not reach them. At this season of the year the aphid or green fly is particularly troublesome, attacking the young growth and exhausting the sap; it is, therefore, of importance that they be kept down, and this can be done in a small collection by sponging them off with weak Tobacco-water; but, in larger collections, where time cannot be spared for removing them in this way, fumigation must be resorted to, although the operation is seldom accomplished

without doing some slight damage to the plants. The chief danger of fumigating is when the material used is allowed to flare; but this difficulty is to be overcome by using a fumigating pot with a lid, which can be obtained at any of the nurseries; it is best to select dull, still evenings for the work, and to fumigate slightly three times in succession rather than once excessively. After fumigating, the house should be carefully shaded the next day, and less air than usual admitted. Coarse, strong Tobacco is undoubtedly the best to use. Liberally supply the New Granada *Odotoglossum*, *Masdevallias*, and other growing plants with water, and see that they do not stand flat on the stages, thereby preventing the free escape of the water. Attend carefully to previous recommendations.—JAMES O'BRIEN.

Indoor Fruit Department.

Vines.—As next year's crop entirely depends upon this year's treatment, see that those Vines from which fruit is gathered receive proper attention, viz., keep the house cool and the foliage healthy and clean until it withers and drops naturally, syringing it well with pure soft water to check red spider and prevent the border from becoming dry. Where manure is considered unsightly, a top-dressing of fresh soil raked over the surface once a week will prevent its cracking and give it a neat appearance. As the lateral growths should now be storing up nutriment for the coming season instead of making young wood, pinch them off. Keep all ripe Grapes cool and dry; ventilate freely and prevent moisture from settling on the berries; except in wet weather never permit the house to be shut up. Vines bearing a full crop of fruit should be well looked after at this particular stage of growth; the borders should be examined often and never allowed to become dry; where sufficient drainage exists they are not easily overwatered. Top-dress twice with cow manure during the growing season, and water copiously with manure-water; red spider will then be rarely seen, and a good crop of fruit will be ensured. Ventilate freely on fine days, front and top air being beneficial, except under strong winds, when the ventilation should be moderated. Vines started late should be looked over often, removing all laterals on their appearance. Avoid the practice of allowing a heavy growth and cutting-out freely afterwards; take advantage of all the light possible, but do not overcrowd. Thin Grapes immediately they can be handled, as the operation can then be performed more quickly than when the bunches have become crowded, as is their invariable habit at this season of the year. Vines planted in the spring, as formerly recommended, will be growing rapidly, and should have daily attention as to tying up the young shoots, pinching out laterals, tendrils, and all unnecessary growths, allowing those side-shoots that are intended to be cut down next year as much light as possible; if for fruit, confine them to a single rod, stopping all laterals at two leaves. Let them receive no check from want of water; ventilate freely in fine weather as a preventive for warts, to which young Vines are very subject, and retain a little air during night. Pot Vines started early will be getting to their full length, and should be stopped 7 ft. from the pot; allow one leaf to each lateral; tie the shoots into their proper places; an abundance of light and air will ensure fruitful canes; avoid over-watering, but do not allow them to droop for the want of it; if insects attack them, hand-wash at once.

Peaches.—Supply fruit-bearing trees continually with water, never allowing them to become dry before the colouring of the fruit, after which gradually withhold water, and keep them dry during the ripening process. Expose the fruit freely to the sun, giving plenty of air; keep the young shoots thinly tied down, giving them all the light attainable. Water well the trees from which the crop has been gathered with a syringe or garden engine frequently during the week, retaining the foliage to the last in a clean healthy state; assist all old trees with manure-water. In succession houses attend to disbudgings, thinnings of fruit, &c.; where the trees are young and growing gross, allow them to carry a heavy crop, which will assist in checking the growth and strengthen the fruit-bearing powers of the trees for the succeeding year. Syringe freely on fine days and water well inside borders; where green fly exists, fumigate well with Tobacco on two successive nights.—J. HUNTER.

Kitchen Garden.

The cold north-easterly winds that have prevailed for the past week or ten days, although to a large extent ungenial, have not been altogether devoid of benefit, as they have dried the ground and thus have assisted in bringing up arrears of seed-sowing, hoeing, and surface-stirring. It is to be hoped, however, that we are on the eve of a change for the better, as the earliest vegetables look most wretched and sadly require warmth both of soil and atmosphere. The season being so late, many of the operations mentioned last week will still require execution, and other operations will continue to pre-

sent themselves, one of the foremost being the preparation of ground that has been cleared of Broccoli for such crops as Celery, late Peas, Carrots, Turnips, &c.; Winter Spinach, as soon as the round or summer kind is ready, should also be dug in; so as to have the ground ready for successional plantings of Cauliflowers and the earliest batch of Savoys, both of which should have prompt attention. Successional plantings of Coleworts and other sorts of Cabbage should be made as ground becomes vacant, and as soon as the earliest are fit to cut, let all the old stumps be cleared away. Another sowing of Peas should be made in quantity according to the demand, and after this it will be advisable to sow them in shallow trenches, especially on light soils; our own practice on light soil is to have all ground on which they are grown trenched; when sown, a deep drill is made with the hoe, and only part of the soil therefrom is used for covering the Peas; the remainder being scattered over the surface of the ground; before staking, the drill is filled to the ground-level only, and the rows thickly mulched with litter or rotten manure. For such soils, surface-mulchings are of immense importance to all vegetable crops, and repay all trouble involved in their application by the extra quality of produce, and the labour saved in watering; sow Spinach between the rows of Peas, and destroy all previously sown as soon as it manifests the slightest tendency to run to seed. Lettuces may now be sown on the ridges formed by making the Celery trenches, and Radishes do equally well in a like position; both require to be sown at frequent intervals, to keep up a constant supply. Seedlings of Basil and Sweet Marjoram recommended to be sown in heat a few weeks ago may now be transferred to the open ground, and all other herbs should be examined, and any that are becoming short should be replaced by division, or seedlings, as the case may be; old plants of Sage and Thyme, if cut over now, will soon make new growth, though it is well to renew them from seed at least once in three years. Parsley will soon require thinning, and, if necessary, another planting should be made with the thinnings. The rows should be 1 ft. asunder, and the plants 6 in. apart in the row. On heavy land, the driest part should be selected for this crop, or it may fail in the winter. If, as in our own case, ground is not likely to be at liberty for some time to come, the earliest-sown Broccoli should be temporarily pitched off, and otherwise encouraged to grow up sturdily; small batches of Walcheren and Snow's should be permanently planted as soon as convenient, in order to insure a supply after the autumn Cauliflowers are over. Should the weather continue dry, Turnips and Radishes will require copious waterings to prevent them becoming hot and stringy. Cauliflowers, also, would be benefited by the same treatment, and these should always have one good watering with liquid manure. I find liberal treatment to be the best preventive of "clubbing." See that Carrots, Turnips, French Beans, and Potatoes in pits and frames have plenty of water, and as the latter are dug up the frames may be utilised for the growth of Chillies, Capsicums, Tomatoes, or Cucumbers, and also for the hardening off of all kinds of plants that are eventually to be transplanted to the open ground.—W. WILD-SMITH, *Heckfield*.

Palm Leaf Water Baskets and Baths.—In Ceylon plaited baskets of Palmyra Palm leaf are made large enough for baths about 3 ft. in diameter and 2 ft. deep. They are double, the inner lining being from the leaf itself, and the outer skin from stripes of the hard central rib of the leaf, termed olah; they are plaited so closely as to be perfectly water-tight, and are sold for about 3s. each. They are made in other shapes, too, for lifting water from wells, and in the north of the island are universally used for this purpose.

The Flora Orientalis.—One of the most important works on descriptive botany in progress is Boissier's "Flora Orientalis," the third volume and first part of the fourth volume of which were published towards the end of last year. The first volume was published in 1867, and the last part issued brings it down to the Boraginaceae. Beginning with Greece it takes in European Turkey up to Dalmatia and the Balkan Range; the Crimea, Caucasus (including the northern slopes), Egypt and Arabia to the tropics, Syria, Asia Minor, Persia, Beloochistan, Afghanistan, and Southern Turkestan, to about 45° N. lat.

Chalk and Ants.—Knowing the feet of the small-sized ant to be so constructed that they could ascend a tree if as smooth as glass, I concluded anything that did not offer a firm footing would prevent their ascension. Reasoning thus, chalk appeared to be the only thing to use. I scraped the bark on the trees in a ring about 2 in. wide around the tree, and then took a piece of chalk and rubbed it on the ring all round the tree till no green bark could be seen, and watched the result. The moment the ants' feet touched the chalk it offered no solid footing; it would fall back and not one could ascend.—JOSIAH CLARK, in "German town Telegraph."

PAROCHIAL FLOWER SHOWS.*

HORTICULTURAL SOCIETIES at present are for lovers of flowers amongst the rich—who want them least. The poorer classes delight in “those stars which on earth’s firmament do shine,” and should, in every way, be encouraged to cultivate them. Our Divine Master was speaking to the poor when He said, “Consider the Lilies.” And it is to the world at large that the great Lesson-book speaks of the Rose of Sharon, the Lily of the Valley, the Oleander by the stream, the Rose of Jericho, the Almond, the Apple or Apricot, the Gourd, the Vine, the Fig, the Olive, the Wheat, and the Darnel, the Cedar and the Palm, and many others, as the Box, the Myrtle, the Willow, the Tamarisk, the Anemone, the Coriander, &c. Plants are the relics of Eden; and on our way to Paradise regained, we may expect very much more than Briers and Thorns. Mungo Park took heart by seeing a tuft of Moss in the desert. Let a man cultivate flowers, and he will find it will often set the chimes going. Canterbury Bells are finer than St. Patrick’s. It would be good for most of us to look oftener upon the Lilies of the field. Every man should, if possible, have his strip of garden. No tenant of even a room should be without a few plants in the window. As far as we are each individually concerned, we must not wait for the Millennium for the wilderness to rejoice and blossom as the Rose. Even in the wildest corners of the land Parochial Flower Shows are quite practicable. In Dublin I have long had an Annual Flower Show, and I would recommend every clergyman to do the same. The following was our list of prizes for 1875.—1. Three Prizes for the largest variety of Wild Flowers. 2. Two Prizes for the best arranged Bouquets of Wild Flowers. 3. Two Prizes for the best Bouquets of Cultivated Flowers. 4. Two Prizes for the largest variety of Ferns. 5. Three Prizes for the best Geraniums given in 1871. 6. Three Prizes for the best Flowers of any kind in pots. (These must have been in the possession of the exhibitor for at least three months.) 7. Three Prizes for the best window-sill boxes of Flowers. 8. Two Prizes for the best written copy of lines on Flowers. 9. Three Prizes for the best Flower Garden. Candidates to send their names and addresses a week beforehand. 10. Also four Prizes for Amateur Workmanship, such as carved work, fancy articles, &c. Now, the above will show how very simply the arrangements may be made and carried out. Several persons in city and country have asked me for these particulars, and several initiated Flower Shows last year, and more have determined to do so this year. With regard to the character of the prizes, this must depend upon circumstances. Plants and books about flowers are what I give as being most appropriate. A good plant, such as an India-rubber plant, or a small Palm, or a Cyperus, or a fine Acacia, are things of beauty and welcome. Until the value of the exhibition was understood, I gave the prizes from my own purse; but now persons gladly assist in defraying the expenses by paying a small fee for admission. I hope the time will soon come when our Horticultural Societies will deign to smile on efforts to cultivate flowers under difficulties, and will offer prizes for small gardens in the smoky city. For the present I must appeal to my brother-clergyman to organise parochial Flower Shows as a real means of blessing.

Gnats in the Garden.—As THE GARDEN must naturally and legitimately take an interest in all that aids or obstructs the progress of gardening, and as ladies are not weak supporters of the objects of THE GARDEN, it would be a real boon to them if any receipt can be given to protect them from the attacks of gnats, which it has been observed have, as well as midges, become much more venomous than formerly, and their attacks have commenced much earlier in the year and continued much later than heretofore; so severe, indeed, are the effects of their stings, that in two or three localities they have actually remained masters of the field, as it has been impossible for ladies to stand in the garden under the infliction; the inflammation, and the bumps raised on the forehead, on the head, the temples, and the cheeks, have caused not only disfigurement, but, in some cases, suffering for days together. There are some few favoured individuals whom they do not attack, or but very slightly; but with others the case is very different. The only thing tried and recommended by a great sufferer has been benzine (the liquid used to take stains out of silk and cloth), which has a very strong scent, but this has been by no means effectual, for the scent very soon passes off in the air, and attacks are recommenced at every vulnerable point wherever the scent is not overpowering on the clothing. Surely there must be something which is objectionable to gnats and midges.—L.L.

TREES AND SHRUBS.

THE CARAMANIAN PODOCOTYTIUS.

THE Caramanian Podocotytus, of which the annexed are illustrations, was discovered in 1855 by M. Boissier, near the village of Güleg-boghas, near the Cilician Gates, growing freely in the calcareous soil of that mountainous region. It is a bushy shrub, of vigorous habit, throwing out a number of strong shoots covered with flowers and leaves. The latter, which are trifoliate and petiolate, are thick and tough, of a pale green colour, and brightly polished on the upper surface. The calyx of the flower resembles that of the Laburnum in form, is of a rusty-red colour, and helmet-shaped. The flowers are bright yellow above, paler below. This charming plant, which begins to flower in July, continues in blossom until autumn, and, on that account, ought to be highly valued, as late-flowering shrubs are by no means plentiful. It may be easily propagated either by means of seed or grafting. If seed be used, it should be sown in March or April in pots or pans filled with light soil. If grafts be employed, they may be put on Laburnum stocks, so as to form either dwarfs or standards, according to taste. Young seedling plants will require to have their roots protected from frost by leaves or litter. Q.

THE BLACK SPRUCE.

The Black Spruce, the common name of this ornamental and useful Conifer, has reference to the very dark green hue of its foliage. Botanically it is known as *Abies nigra*. Its home is in the northern and eastern parts of North America. It is said by Michaux to be found in its greatest abundance between 44° and 53° of north latitude, and 55° and 75° of west longitude. This would include the southern part of Labrador, the Rupert River region, the provinces of Quebec, Nova Scotia, and New Brunswick, all of Maine and the northern part of New Hampshire, Vermont, and New York. Its real range, however, is much greater than this, for it extends southward along the Alleghany Mountains as far as North Carolina, westward to Wisconsin, and northward to the 65° parallel, ceasing to grow but a few degrees this side of the Arctic circle. It delights in cold, hilly and mountainous regions, attaining its largest size and growing most abundantly on those moderate elevations, ridges, or slopes where the soil has a ready drainage and at the same time retains considerable moisture by reason of its mossy, shaded surface and gooly percentage of dark vegetable mould. No matter how rocky the soil, the tree still flourishes. It also grows freely in low swampy lands and about sphagnum marshes, but in such localities it is inferior in size and quality. The Spruce, as it occurs in the forest, usually attains an altitude ranging from 50 to 80 ft. and the basal diameter of the trunk is from 1 to 2 ft.; but occasionally trees are found that have a diameter of nearly or quite 3 ft. The trunk is comparatively straight, very gradually tapering upwards and free from branches two-thirds to three-fourths the entire length of the tree. It is covered with a thin grayish-brown bark slightly roughened with small scales. This is not deemed valuable for tanning purposes, but it affords a very good covering for shanties and the log houses of backwoodsmen. The altitude of the tree increases by the annual growth of a single leading terminal shoot, which in young and moderately vigorous trees advances about 1 ft. in a season. This mode of growth is characteristic of all our Pines and Spruces. As this terminal shoot pushes its way upward it sends out annually from its base a whorl of branches. These branches are gradually shorter as we pass from the lower to the upper whorls, each successive one having one year’s less growth than its immediate predecessor. They, therefore, as a whole, give to the tree a more or less regular conical outline. In process of time the lower branches decay and drop off, thus leaving a naked trunk. It is this peculiar mode of growth that makes these trees so available for ship masts and flag-staffs. The branches of the Spruce are directed slightly upwards and are surrounded on all sides by the leaves. These are usually about half an inch long, somewhat quadrangular and very narrow or needle-shaped. They remain on the branch about five years. The cones are pendent, ovate or oblong-ovate, three-fourths of an inch to 1½ in. in length, and are somewhat variable in colour before maturity. The shape of the cones serves as a convenient character by which to distinguish the Black Spruce from the White, whose cones are narrow and almost cylindrical. The wood is light and strong, and has considerable elasticity. It is of a brighter colour than either the wood of the Pine or the Hemlock. Though decaying quite rapidly when exposed to the weather it is quite durable when protected. It constitutes an important element in the lumber trade. Spruce boards are deemed more valuable than Hemlock but less

* By the Rev. Alfred Clayton Threlton, Incumbent of the Episcopal Chapel, Upper Baginot Street, Dublin. In the “Irish Church Advocate.”

* Read before the Albany Institute, by Charles H. Peck

THE CARAMANIAN PODOCYTISUS (P. CARAMANICUS).

valuable than Pine boards, because of a greater liability to warp and crack. They are harder than Pine and are therefore more difficult to work. Spruce is sometimes used for the frames of buildings and for floor timbers, but generally it is cut into boards, door or window casings, siding, flooring, &c. In some localities the making of Spruce shingles is an important branch of industry, but such shingles are generally considered inferior to those made from Pine or Hemlock. From the New York census returns for 1865, we learn that the amount of Spruce lumber produced in the preceding year was 71,000,000 ft., more than six-sevenths of which was produced by the counties bordering on the northern forests. The value of this at 20 dols. a thousand would be nearly 1,500,000 dols. The lumbermen of these northern counties go far back in the woods along the principal streams, cut the logs and draw them to the water-courses. In the spring, when the water is high, they are floated down the stream to the mills where they are to be sawed. In this way deep inroads have been made in the forests so that they are not now the vast unbroken wilderness they seem. To one passing along the Upper Hudson or the valley of the Sacandaga in summer time, the numerous piles of Spruce logs that have lodged against rocks or on low banks, speak plainly of the rapid destruction of the Spruces and of the swiftly contracting areas that are darkened by their shadows. And yet these are but the small portion of logs that fail to get through to their destination while the spring freshets last. If we suppose 5000 ft. to be the product of an acre it would require more than 14,000 acres to furnish the 71,000,000 ft. above mentioned. In the vicinity of Rock River, in Hamilton County, many large Spruces have been left standing on land cut over by lumbermen. Why were these trees left? An examination of the trees reveals the fact that they are affected by what lumbermen call seams. A chink or crack extends along the trunk following the course of the grain of the wood. If the grain be straight the seam also is straight, if the grain be oblique the seam winds obliquely round the trunk. They sometimes extend nearly the whole length of the trunk. They penetrate the wood deeply, often reaching nearly to the centre, and they therefore detract much from the value of the tree for lumber. Such trees are consequently left standing when they grow far from the lumber market. If the tree be crossed-grained, the seam renders it worthless except for fuel. Externally these seams are bordered by a more or less abundant exudation of resin, which in its dried or hardened state is popularly known as Spruce gum. It is not improbable that the permanent character of the seam is due to the presence of the gum which prevents the healing of the injury. This gum is generally coated by a velvety stratum of black fungoid filaments, which give a blackish appearance to the seams. Electricity and excessive cold have been suggested as possible or theoretical causes in the production of seams, but neither is to my mind wholly satisfactory. When electricity rends the bark of a tree it carries the injury to the ground, losing itself in the earth, but the Spruce seams generally cease before reaching the extreme base of the tree. Besides, a tree struck by the electric current seldom survives the shock, while seamy Spruces live and thrive. Probably not more than one tree in fifty, on an average, is seamy. Why, then, should one tree be checked by excessive cold, while forty-nine others in the same locality and exposed to the same temperature remain unharmed? It is barely possible that an unusually thrifty growth or an excessive surcharging of the tender tissues of the sapwood with moisture might give rise to conditions in which intense cold would produce a rupture, but it is hardly probable. It would appear to be an easy matter to determine the cause of the seam by an investigation in its earliest stage or soon after its commencement, but I have never yet seen one in such a condition, and do not deem it worth while to waste time in speculating upon the cause of this curious feature.

Types of Black Spruce.

A complete knowledge of the Black Spruce requires an acquaintance with its varieties. Some plants are much more fixed and uniform in their characters than others. The Spruce is much more disposed to be variable than the Hemlock. Some varieties depend upon external conditions, circumstances, or influences, which are easily detected; others seem to be constitutional or inherent in the plant itself. Their causes are not easily discernible. To one familiar with our evergreen forests the ideal or type of the Spruce is that of a noble tree with a tall, straight, erect trunk supporting a somewhat conical head of dark green spray. But the tree varies greatly from this type according to its age, the character of the soil, and the altitude of its station. In young trees growing in open places or on cleared lands it is common to find the entire trunk occupied by branches, the lowest whorl being but slightly raised above the surface of the earth. This differs from the young trees of dense woods only in retaining its lower branches for a longer time. In open sphagnous marshes a form occurs so marked in its appearance that in some local-

ities it has received the name of Bastard Spruce. The branches, which frequently occupy the whole trunk, are generally very slender, the internodes short, and the leaves pale. The tree has a feeble, starved, or sickly aspect, and does not attain a large size. A cross section of the trunk shows the concentric rings which mark the annual growth of the wood lying close together, which, with the short internodes of the branches, indicate a very slow growth. These trees are too small to be of any value. They are rarely fertile. In wooded swamps and low lands a larger form is common. It scarcely differs from the ordinary forest tree except in its inferior size and quality. It affords a poor quality of wood, and is sometimes cut into piles to be used in the construction of dykes and foundations of bridges and large buildings. It is not worth much for lumber. It is intermediate between the Bastard Spruce and the Forest Spruce, having the distinct trunk of the latter and the starved, unthrifty look of the former. Another form occurs in the Adirondack region, and is said to grow also in New England. The foliage has a silvery or glaucous hue, on which account it is sometimes mistaken for the White Spruce. Its cones, however, have the shape of ordinary Black Spruce cones, and enable us to correct a very natural mistake. The cause of this variation is not easily perceived, unless it is the result of cross fertilisation between the Black and the White Spruce. The two preceding forms manifestly depend upon the character of the soil. A large form with cones of unusual size and wood of soft texture was once described as a distinct species. It received the name *Abies rubra* or Red Spruce, but it is now deemed only a variety of the Black Spruce. Its range is northward. According to Michaux, in Nova Scotia its wood is used in making fish barrels, on account of the ease with which it is worked. But the most remarkable variety is found on the highest summits of the Adirondacks. Remarkable as it is, I have seen no description nor even mention of it in botanical works. It is the variation of the tree into a mere procumbent shrub, so small that it offers but little impediment to him who would walk over it. These bushes are more or less flattened in outline, the branches issuing mainly from the two opposite sides of the trunk as in the Ground Hemlock. They grow in dense patches completely covering the ground, and in numerous instances with their apices all pointing the same way. They have the short internodes and the short pale leaves of the Bastard or sphagnous marsh variety. Sometimes the leaves are tinged with a glaucous hue as in the variety previously mentioned. I have never seen cones on this dwarf form, nor is it probable that it ever produces them. Its stunted form speaks plainly of the struggle of a hardy plant for existence in unfavourable conditions. A thin soil, the prevailing low temperature of high altitudes, fierce blasts of winds and the crushing weight of heavy snows all conspire to keep down anything like successful tree growth on the tops of these mountains. The two extremes of the Black Spruce have now been noticed. The one a noble forest tree 50 to 80 ft. high, with a well-formed trunk 1 to 2 ft. in diameter at the base, supporting a symmetrical top or head of branches covered with dark green leaves; the other a dwarf of the mountain top, scarcely a foot high, with no distinct trunk and without strength to maintain an erect position, its stunted branches spreading two ways and bearing short, yellowish-green leaves, the whole looking very much as if it were a feeble branchlet of the former thrust obliquely in the ground. What thoughts do they suggest concerning the variability of the species, what concerning its stability? Surely a remarkable degree of variation, a singular tenacity of life, and a wonderful power of adaptation to alter conditions are manifest. The Spruce shows itself capable of maintaining an existence under most adverse circumstances.

Spruce Mistletoe.

Perhaps no plant is wholly free from the attacks of parasites, but some are much more liable to these attacks than others. One species may be subject to the attack of a single parasite, another, of a half-dozen or more. I have sometimes thought that the greater the susceptibility of a plant to variation the greater its liability to parasitic attacks. Certainly the variable Black Spruce is obnoxious to many parasitic foes. *Arceuthobium pusillum* is one of these. Like many other parasitic plants it is destitute of true leaves. Botanically it is related to the Mistletoe, and, by way of distinction, it might be called the Spruce Mistletoe, since it is thus far peculiar to that tree. It often occurs in abundance, fringing the younger internodes of the living branches by the multitude of the plants. Having once attacked a tree it continues to prey upon it year after year, growing with its growth and thriving with its thrift. The remarkable fact about it is that thus far it has been detected on those Spruces only which grow in swamps or on and around sphagnous marshes. It has not yet been seen on the typical forest Spruce. Though this plant was first discovered but little more than three years ago, it is now known to occur in five counties of the State. I have not heard of its discovery beyond the State boundaries. It is not positively known to kill the tree which

it attacks, but it is probable that it sometimes does. Dead trees occur which bear the marks of its former presence.

Spruce Destruction through Pine Beetles.

In August a collecting trip was undertaken in the vicinity of Lake Pleasant, Hamilton County. While there it became apparent to me that I was in a region where the Spruces were dying. Standing near the outlet of the lake and looking upon the distant mountain slopes toward the north-east, east, and south, patches of brown appeared here and there mingled with the usual dark green hue of the forest. The inhabitants told me that these brown patches were groups of dead Spruces, that the Spruce trees were then rapidly dying and had been for two or three years previously, and that in consequence the value of the woodland was greatly diminishing. One of the most conspicuous of these brown patches was on the slope of Speculator Mountain, a little more than half-way from the base to the summit. Preparations were therefore made to visit this locality. Once on the ground it needed but little observation to satisfy me that the destructive process was then in operation. The ground under some of the Spruces was thickly strown with their fallen leaves, yet green, and every agitating wind was bringing down more of them. The bark of these trees and of others already dead was perforated in many places with small round holes scarcely $\frac{1}{2}$ in. in diameter. Upon stripping a piece of bark from the trunk of one of the affected trees, the apparent cause of the mischief was at once revealed. The surface of the wood and the inner layers of the bark were abundantly furrowed by the winding and branching galleries of a small bark-mining beetle, an insect known to entomologists as the *Hylurgus rufipennis* (Kirby), though the wings are by no means always red as the name would indicate. Both the mature insect and its larvae occurred in countless numbers under the bark of the dying and recently dead trees. In a single instance they were accompanied by a much smaller beetle of similar shape and habits, the *Apatz rufipennis* (Kirby), but the former is evidently the chief agent in this unprofitable business. These insects excavate their passages between the bark and the wood, eating away a part of both. Their extended work is therefore equivalent to a girdling of the tree. Their numerous galleries form an intricate network of furrows on all sides of the trunk, and traverse one of the most vital parts of the tree, the newly formed and forming layers of wood and bark. The furrows are shallow on the surface of the wood, rather more than half their diameter being in the bark, but their effect is to interrupt the circulation of the nutrient juices, and finally to destroy all vital action. The perforations in the bark, by admitting moisture, doubtless work more or less injury. The surface of the sap-wood and the corresponding inner surface of the bark of living trees are discoloured for a short space on both sides of the furrows, as if the injury exerted a poisonous or deadening influence on the tissues in its immediate vicinity. This was clearly seen in a tree which had been but slightly injured, there being but few furrows, and those merely longitudinal ones without lateral branches. Each occupied the centre of a discoloured stripe about $\frac{1}{2}$ in. broad, but which usually extended from 2 in. to 4 in. up and down beyond the extremities of the furrows. In another tree there were groups of furrows separated by considerable intervals, the central portions of which intervals had a whitish, fresh appearance when the bark was first peeled, but after a few moments of exposure to the air the whole surface of the wood had changed to a dull, dead, brown colour, indicating a diseased or unnatural condition of the surface tissues. The foliage on this tree had not yet lost the green hue of life, but had commenced falling to the ground. Small trees are rarely attacked. In the localities visited, from one-half to two-thirds of the Spruces with a basal diameter ranging from 1 ft. to 2 ft., were either dead or dying. Trees of this size are the most suitable for lumber, and consequently the most valuable. The smallest affected tree noticed had an estimated basal diameter of about 10 in. In this case the attack appeared to be a failure, for so much resin had oozed from the wounds that the work was obstructed. The galleries were scattered and single, and their authors were found dead, each in its furrow. No larvae were present, and the apparent attempt to establish a colony in this tree had thus far failed. But it may be that this tree had only been attacked for the purpose of obtaining food, and had not yet been brought into that sickly, languishing condition thought by some entomologists to be necessary to induce the establishment of a colony, the deposition of eggs, and the development of larvae. For it is said of the *Scolytus* destructor, a bark-mining beetle that sometimes proves very destructive to Elm trees in Europe, that the adult insects first attack healthy trees for the purpose of obtaining food, and when by this means the vigour of the tree has become somewhat impaired, the female deposits her eggs in her galleries. Then the rapidly increasing numbers soon destroy the life of the tree. In the vicinity of Lake Pleasant the affected trees are upon the mountain slopes or on dry ridges where the Spruces

are especially abundant. And we might naturally expect that the insects would be attracted to and carry on their depredations most extensively in those localities where the material on which they work is most abundant. In the valleys I saw no trees affected by them, and yet they doubtless carry on their destructive work in the low lands where Spruces abound. I see no reason why they should not. In some localities their ravages have already ceased. On the slopes of an elevation a few miles south-west from Speculator Mountain there are two groves of dead Spruces. Many trees in both were examined, and, though all the dead ones bore unmistakable marks of the former presence of the beetle, not one could now be found either in the adult or in the larval state. What had caused them to disappear? Surely not the lack of material on which to work, for several large living Spruces yet remained. This leads to the consideration of remedies. Doubtless there are natural agencies whose free operation has a tendency to check the ravages of these insects and to prevent their excessive multiplication, but there are times and localities in which these opposing agencies are inefficient or inoperative, and then these destructive insects multiply rapidly and their ravages become painfully apparent. It is then necessary that man himself should do something to protect his property from these active little foes. It was noticeable that many of the dead trees in the two groves just mentioned had their bark so chipped by woodpeckers that the general hue of the trunk was a reddish-brown instead of the usual grayish-brown. Here then is a possible explanation of the cessation of the ravages and the absence of the insect. Here is doubtless the indication of one of Nature's antidotes to the mischief. The woodpecker is the natural foe of such insects. With its long beak and barbed tongue it extracts them as a dainty morsel from beneath the bark. It is quite probable that these birds had congregated in these two localities in sufficient numbers to completely stop the ravages of the insects. A few were seen at work on the affected Spruces of Speculator Mountain, and if not interrupted they will probably in due time succeed in checking the ravages there also. The protection of these birds is to be enumerated among the means to be employed in checking the malady of the Spruces. They are the friends of the forests and the allies of man. How insignificant the insect, yet how capable of injury! How lightly we esteem the woodpecker, yet how indispensable are his services!

Abies Engelmannii or *commutata*.—In reply to your query, "Is this tree in cultivation in England?" allow me to say that in nurseries at least it is very well represented by plants varying from a few inches to 3 ft. in height. Our tallest plant measures 3 ft. 10 in. It is of moderate growth, which, combined with its dense, broadly-conical habit, and the intense blue of its rather long, formidable foliage, together with its unprecedented hardness, render it one of the best, if not the best, of ornamental Spruces. I have never seen it attacked by any of the insects that often render plants of the same heights of other species of Spruce unsightly. When better known it will be found in its proper place, dotting and beautifying the lawn and pleasure grounds of both Britain and Ireland.—G. S., *Elvaston Nurseries, Borrowash*.

Kerria japonica on Walls or Pillars.—Although this well-known shrub will flower freely under even the most adverse circumstances, and will grow in the very poorest of soils, yet it well repays a little extra attention. It forms a handsome bush in shrubbery borders, but it is upon the whole, perhaps, most effective as a wall or pillar plant, either intermixed with or closely associated with the *Cydonia japonica*, both flower at the same time, and their colours, harmonising well together, produce a striking effect. It is readily increased by division of the roots or by cuttings. As regards pruning, by cutting out the old flowering shoots annually and encouraging the strong shoots that spring from the base, much finer blossoms will be secured than if left undisturbed.—J. Groom, *Henham*.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The White Wistaria.—This is now in London gardens the queen of hardy climbers, its long and graceful racemes unfolding without much injury from the cold winds. It deserves to be as frequently planted as the blue kind, which I train as a self-supporting pyramid on the lawn as well as on walls.—V.

The North American Sylva.—Over 300 trees and more than 800 wood species of plants are believed to be embraced in the flora of the United States, and of the trees 250 species are tolerably abundant in one region or another, 120 of them growing to a large size.

Robinia hispida.—Can any of our readers procure specimens of the fruit of this plant for Professor Gray, of Harvard University, Cambridge, Mass. ?—

THE FRUIT GARDEN.

REMEDIES FOR THE VINE PEST.

IN a recent number of the "Annales de Chimie et de Pharmacie," M. Dumas, one of the most celebrated of living chemists, publishes a long and elaborate article on the best means of destroying the phylloxera or Vine pest. About five years ago M. Dumas, was deputed by the French Government, in company with several other eminent chemists, to investigate the action and efficiency of the numerous remedies proposed for the destruction of this insect, and he gives us full details of all his experiments in the article in question. It is, however, rather with results than experiments that we have to deal, and the outcome of M. Dumas' labours is that there is no remedy so thoroughly effectual and convenient as a solution of a salt known to chemists as the sulpho-carbonate of potash. Amongst other remedies proposed the most efficient seemed to be the bisulphide of carbon, a thin, volatile, transparent liquid obtained by passing the vapour of sulphur over red-hot charcoal, which is much used as a solvent of india-rubber. Holes, 2 ft. or 3 ft. deep, were made with a crowbar or auger in the earth around the roots of the Vine attacked by phylloxera, and a certain quantity of the liquid was poured in which, by gradually diffusing itself amongst the roots, effectually destroyed the pest. But there were many objections to the use of this remedy. Its easy inflammability and its noxious vapour rendered its use extremely dangerous; besides which it not only killed the phylloxera, but seriously injured the Vines. M. Dumas' experiments soon led in the direction of the sulpho-carbonates, and he ultimately fixed on the sulpho-carbonate of potash, as we have said, as the most fitting salt. This salt, which is, roughly speaking, a compound of sulphur, carbon, potash, and water, is exceedingly unstable, and becomes decomposed even by the slight proportion of carbonic acid that is in the air. It is applied in the form of a weak solution by means of holes bored in the soil. As the liquid penetrates amongst the roots, the carbonic acid, which is always contained in the rain-water which has percolated the soil, decomposes the salt—the vapour of bisulphide of carbon and gaseous sulphuretted hydrogen being given off, and carbonic acid taking their place. Both bisulphide of carbon and sulphuretted hydrogen are poisonous to the phylloxera, and as the change takes place gradually, the danger of injury to the Vine itself is not so great. When all the sulpho-carbonate is spent it becomes changed into bicarbonate of potash, a powerful fertilizer, so that the insecticide, having done its work, becomes transformed into manure.

The sulpho-carbonate of potash is rather dear at present, but, as its use increases, it will become cheaper. It does not seem to have entered the London market yet, but the Paris price, as quoted by M. Dumas, is 200 francs per 100 kilogrammes, or rather less than 10d. per lb. At any rate, any large wholesale chemist would be able to procure it. The best way of using it is to have a solution made having a specific quantity of 1-357, which should be prepared by a chemist. A pint of this solution mixed with two or three gallons of water should be used for each square yard of surface. If the ground be very dry, the quantity of water may be increased to six or even eight gallons, but this must be left to judgment and experiment. Half-a-dozen holes, 2 ft. or 3 ft. deep, should be bored round the Vine and the liquid poured in, fresh being added as it is absorbed by the soil. Three months after the same dose should be repeated. As a rule, early spring and autumn are the best seasons for applying it, but if the pest be discovered to be at work any time before July the sulpho-carbonate should be resorted to at once, as the winged insect reaches maturity in that month. If discovered in the winter, the treatment should not be delayed beyond the beginning of March, when the insects are just waking from their winter sleep. French Vine-growers object to the use of sulpho-carbonate of potash on account of its dearth. This may be an obstacle in a country where, as happened last year, the Grape crop was so large that thousands of tons rotted on the ground because there were no casks to put the wine in; but in England the case is very different.

C. W. QUIN.

Grapes Over-thinned.—Many thin their bunches of Grapes too much in the centre, according to Mr. Douglas, writing in the "Journal of Horticulture." The result of this is to spoil the appearance of them when they are placed upon the table—they "fall all over the place" instead of lying compact and firmly as they ought to do. A fruit salesman told us that a certain grower always had a good price for his Grapes, because the berries stood up so firmly in the baskets owing to the correct manner in which the berries were thinned out. Those bunches that are too much thinned fall about, and the bloom is rubbed off the berries. It is difficult to teach any

one to thin Grapes by writing about it. Everyone must learn from experience. Even a practised man is sometimes at fault until he knows to what size the berries are likely to grow.

A NON-PATENTED APPLE BARREL HEADER.

APPLES require to be packed very firmly in order to enable them to travel with safety; for, if loosely packed, they come to market in a bruised condition. Apples may be allowed to fill the barrel to about 2 in. above the rim, and will bear to have the head brought down to its place. Thus packed they may receive very rough usage without injury. The header referred to consists of a bar of half-inch square iron rod, with a large eye or loop at one end, and at the other end two diverging hooks which grasp the bottom of the barrel. The bar is bent to fit the curve of the barrel. When in use, the hooks are placed beneath the lower rim of the barrel, one end of a short lever is placed in the eye, and the lever rests upon a block, which is set upon the head of a barrel properly placed in position. A strap or cord, with a loop or stirrup at one end, is fastened to the other end of the lever. The foot is placed in the loop or stirrup, and the weight

of the body thrown upon it brings the head or lid of the barrel in its place; the hands being free, the hoops can be driven down tightly without the help of an assistant. Without the use of the cord and stirrup, two persons are required to head barrels, but with the aid of these the services of one can be dispensed with.—"Canada Farmer."

WILD AMERICAN GOOSEBERRIES.

I.—LET us begin with the species which a gardener might say was a cross between a Gooseberry and a Currant, namely—

Ribes lacustre, well marked by having racemes of numerous small flowers, in the manner of a common Currant, the blossom as small and as open, and the very small reddish berries beset with some scattered bristles. This abounds through the north, in cold wet woods, from Newfoundland to the Pacific. There is a dwarf variety of it in the higher Rocky Mountains and north-westward, smaller in all its parts, and with fewer flowered racemes. In some publications I have called it *R. setosum*, a species said to have been raised by Loddiges from seed sent by Douglas. It was received from Messrs. Loddiges under that name thirty years ago, and cultivated in the Cambridge Botanic Garden. Yet it is not the plant published and figured by Lindley, as will be presently seen. I pass to—

II.—The true Gooseberries, with peduncles bearing only one or two at most four flowers, and calyx-cup bell-shaped or tubular. These may be roughly arranged in three sets by the colour of the flower.

(1.) Yellow-flowered. The only one of this subdivision is—

R. leptanthum.—It belongs to the Rocky Mountains of Colorado and New Mexico, and to the drier parts of the Sierra Nevada. It was first collected by Dr. Edwin James in Long's expedition, but was named and described long afterwards, from Fendler's New Mexican collection. It is an insignificant, small-leaved, and slender-flowered species. The dried flowers do not seem to have been really yellow, but they are said to be so by the collectors in the Sierra Nevada, where, however, the flower is generally shorter, broader, and more downy. We would ask those who have met or may meet with it in the Rocky Mountain region if the flowers be really yellow or yellowish there.

(2.) White or greenish flowered, sometimes with a dull purplish tinge. To this division belong all our eligible Gooseberries, and here lie the main difficulties in the way of distinguishing the species. Two of these may be known from the rest by having the lobes of the calyx

decidedly shorter than the tube, and their berries are apt to be prickly. They are—

R. setosum, a white-flowered species, with a narrow cylindrical calyx-lobe. It takes its name from the slender scattered prickles on the branches; but these are sometimes wanting, this being an inconstant character in all the species. The young berries are either perfectly smooth and naked, or beset with a few bristly prickles. This is the *R. oxyanthoides* of Hooker's Flora, but certainly not of Linnaus. It belongs to the Saskatchewan region, extending into Montana and Wyoming. No. 107 of Dr. Parry's Wyoming collection is a small-leaved form of it, which was mistaken for *R. leptanthum*; but the flower is perfectly smooth, evidently white, and the style deeply cleft and hairy towards the base. I suspect that this species inhabits the north-western shore of Lake Superior. Botanists visiting that district should look for a species with pure white flowers, a half-inch or less in length, with cylindrical tube, and stamens decidedly shorter than the lobes.

R. cynosbata.—This Dogberry, as the name denotes, is well marked by the usually strong prickles on the fruit, weak prickles on the stems (the thorns sometimes wanting altogether, but occasionally well developed), slender peduncles, and especially by the broad bell-shaped tube of the greenish flower. It is common from Lower Canada to Illinois, and in the Alleghanies to Virginia. It is found occasionally with the berries as well as the stems wholly unarmed. In the rest of this section the calyx-lobes are decidedly longer than the short, bell-shaped tube; and the berries are smooth and naked, purple, sweet and pleasant-tasted.

R. gracile is the most distinct of them. It is well named on account of the slender peduncles, long and narrow calyx-lobes, and almost capillary filaments. The latter are half an inch long, generally connivent or closely parallel, and soon conspicuously longer than the oblong linear calyx-lobes, which, being reflexed in anthesis, as in all these species, then expose the whole length of the stamens to view. The flower is whiter than in the rest of these species, having barely a slight tinge of green. The berry is pretty large, and is prized in cultivation under the name of Missouri Gooseberry. It is the *R. Missouriense* of Nuttall in Torrey and Gray's Flora. It is also, as the figure shows, the *R. niveum* of Lindley in the "Botanical Register;" and from the character it is probably the *R. triflorum* of Hooker's Flora. It ranges from Tennessee and Illinois to the northern borders of Texas, and north-westward into the Rocky Mountains. In Michaux's Flora the habitat is the mountains of Tennessee; but I suppose it will not be found in the Alleghanies.

R. rotundifolium is a species of the Alleghany Mountains, ranging northward and eastward into New York and the western borders of Massachusetts. Prof. Dewey long ago collected it near Williamstown; and Prof. Tuckerman's Amberst catalogue gives West River Mountain, on the authority of Hitchcock. I wish to obtain flowering specimens of it from all parts of its range; for the limits between it and the following are obscure. Its range is more southern and comparatively restricted; the flower is narrower, and the stamens longer, becoming a quarter of an inch in length and nearly double that of the calyx-lobes; the peduncles also are longer; but this character does not hold out well. Although it belongs to a district most of all familiar to botanists, I have seen few flowering specimens of it. A specimen is preserved in the Torrey herbarium, and is the European Gooseberry. *R. triflorum* Wild is, I think, rightly referred to *R. rotundifolium*, an earlier name.

R. oxyanthoides.—We must bring this name into use in place of *R. hirtellum* (which is generally inappropriate), for no reasonable doubt remains that it is the Hudson's Bay Gooseberry, figured by Dillenius, upon which Linnaus founded the species. It is the common smooth-fruited Gooseberry of New England and the whole region northward, and it extends westward to and beyond the Rocky Mountains, and even into the Sierra Nevada of California. It has shorter peduncles than the preceding, but this distinction is by no means absolute; the flower is broader, and the stamens merely equal or only slightly exceed the calyx-lobes. It is the *R. saxosum* of Hooker, whose *R. oxyanthoides* is *R. setosum*, while that of Michaux is *R. lacustre*.

R. divaricatum, of Douglas, takes the place of all the preceding on the Pacific side, and ranges from the lower part of California (in a downy form, *R. villosum* of Nuttall) to British Columbia, meeting *R. oxyanthoides* in the interior. There is a form (the var. *irriguum* of Douglas), of which we know too little, which comes near to *R. rotundifolium*. The species is pretty well marked by its slender peduncle and pedicels, three to four flowered, oblong and livid-purple calyx-lobes, and short and broad tube; the stamens about a quarter-of-an-inch long, and thrice the length of the broadly-wedged and nearly white petals. The flower, ovary included, is from a third to half-an-inch long. The berries are said to be excellent.

(3). Red-flowered species. These all belong to the Pacific side of the Continent, are large-flowered, and their berries are unfit to eat.

R. Lobbi.—I am under the necessity of giving a name to this little but apparently very distinct species. It is figured in the "Botanical Magazine," t. 4931, as *R. subvestitum*, from a Californian plant sent by the late Mr. Lobb to Messrs. Veitch & Son. It should be particularly looked for in California, north of San Francisco Bay, and along the coast to British Columbia. Perhaps the Californian habitat is an error. The species may be distinguished by its dark, purplish-red calyx of half-an-inch in length, not counting the ovary, nearly white petals half the length of the stamens, very glandular but unarmed ovary, and especially by a few warty glands on the back. These short and blunt anthers are shared with all the preceding species, but not with the following.

R. Menziesii, well marked by its sagittate anthers, with a mucronate tip. The flowers are as large as in the preceding, or considerably larger, but variable in this respect, and of a similar purplish-red colour; and the berry is large and prickly, usually densely, sometimes sparsely so; the prickles sometimes strong and spiny, sometimes shorter, bristle-like, and when young gland-tipped. It extends from the southern part of Oregon through the whole length of California, and varies exceedingly. *R. subvestitum* of Hook and Arn., as to all the specimens of Douglas, on which it was founded, is a form of the species not far removed from the typical. *R. californicum* and *R. occidentale* of Hook and Arn. seem different enough in the original and in many other specimens, being very small-leaved and mainly glabrous. I had formerly (in the fourth volume of the "Pacific Railroad Explorations") united these two with *R. subvestitum*. I am now of opinion that all are forms of *R. Menziesii*. They are, however, commended to the notice of native Californian botanists.

R. speciosum.—The Scarlet-flowered Gooseberry of California is so distinct that a separate section has been provided for it. Besides the bright colour and ample size of the flowers, its calyx-lobes do not turn back, and are often only four; the stamens protrude for an inch or more, and the rather dry berry is few-seeded. Its synonymous names are characteristic: *R. stamineum* of Smith, for the remarkably long stamens; *R. fuchsoides* of Berlandier, for the resemblance to a Fuchsia-blossom. In England, where it is hardy, it is prized in cultivation for its brilliant red flowers, garnished by the shining and almost evergreen leaves. Trained to the wall of a house, it may be carried to the height of 15 ft. or 20 ft.—ASA GRAY, in "American Naturalist."

Rust on Grapes.—In my opinion Mr. Smith (see p. 444) is mistaken when he says that rust occurs when Vines are in bloom, or when Grapes are setting. If rust occur at such an early stage of growth, why does it not make its appearance sooner on the berries than it does? Perhaps Mr. Smith will enlighten us on this point. My Grapes had not a particle of rust on them until quite the end of April, since which time they have gradually got worse. They are now colouring fast. I am aware that a dry atmosphere is not necessary for Grapes when in bloom, or when they are setting, and for that reason the atmosphere of my house has been kept moist since I first started it. I am certain, therefore, that a parched heat has not caused the Grapes to rust in my case.—G. H. G.

The Woolly Aphis, or American Blight.—M. Charles Joly, the Vice-President of the Central Horticultural Society of France, gives a remedy for woolly aphis, which seems more promising than the thousand-and-one panaceas which are so constantly proposed for eradicating this troublesome pest. 7 lbs. of soft soap, 1 lb. of train oil, two or three handfuls of soot and flour of sulphur are to be mixed with a pailful of lime-water. When thoroughly incorporated, throw in sufficient powdered clay to make the mixture of the consistency of batter. Spread a cloth beneath the affected tree, and scrape off all the Moss and bark which seem to be attacked by the aphis, taking care to trim the rough portions of the bark, and to clear out the crevices. Remove the cloth, and burn everything that has fallen on it, and paint the whole of the trunk of the tree and the lower branches with the soap mixture, giving an extra dose to all crevices and cracks. Antaim is the best time for the operation, as the winter rains wash the soap mixture off the tree down to the roots, amongst which a few of the aphides that escaped the soap mixture may have taken refuge. It cannot be too frequently repeated, that the woolly aphis always takes up its winter quarters round the collar of the root—a fact that is too frequently lost sight of.

STORING LOAM.

In the culture of exotic plants and fruits no material is so generally indispensable as loam; it forms the staple of nearly every compost, and as it is very variable in character, it is needful to get it of the best quality, otherwise mistakes are sure to be made in making up composts; for what may be reckoned heavy or light loam in one district, may be a very different material in another, both mechanically and chemically. The top spit of old pasture land is the kind of turfy loam which a cultivator prefers to all others; but it may be heavy or light, brown or yellow, sandy or calcareous, according to the formation which underlies it—in some cases so light as to be fit for the culture of the most tender subjects, without additions in the shape of leaf-mould, peat, or sand; and in other cases so heavy as to be useless for most purposes by itself, but an excellent loam when mixed with any of the ingredients just named in the right proportion.

Strong loam is the accepted name for that yellowish, somewhat adhesive soil, deficient in sand, which is usually considered proper for Wheat. It is not often formed upon a gravelly, chalk, or sandy bed, but more generally upon the clay itself, and in some places upon blue clay, or on those shaly formations, highly impregnated with iron, which sometimes overlie the coal measures—as in some parts of Yorkshire, where a very strong but good loam is found, that suits such subjects as Vines and Peaches, and, when reduced with lighter composts, all kinds of stove and greenhouse plants, particularly Cinerarias and Calceolarias, and other subjects which prefer a cool soil. On the same formation the Bramble renders the woods almost impassable for miles, and in some places the Elderberry is equally rampant, and the common Wood Hyacinth and Foxglove may be seen flourishing as they do nowhere else, while in the open fields Buttercup and Daisies, the Cock's-foot and similar Grasses, invariably indicate the same kind of soil, which, however, is generally thin and naturally well drained. It has been said that where such timber trees as the Beech, Oak, Elm, and Spanish Chestnut thrive, the soil is generally good; but for horticultural purposes such trees are not a safe guide, for they all thrive and live long in soils of very different character. Specimens of the above, which it would be difficult to excel, are found growing indiscriminately in chalk and limestone, almost pure sandy soils, and in both the strong yellow and red loams. The surface vegetation is the best guide. A good stiff sample of Wheat, Docks, Nettles, the stronger-bladed Grasses, Daisies, and Dandelions in abundance, and a rather coarse sward, usually indicate a heavy loam, and, accordingly as they predominate or otherwise, its texture may be pretty correctly judged.

Time for Obtaining and Storing Soil.

Cultivators do not care to get turf, whether peat or loam, when it is sodden, but like it to be moist, and rather than store it in a dry state, would prefer to have it wet. Most people know how difficult it is to soak a body of soil when once it has become thoroughly dry, in which condition turf often is when taken off the pastures in summer, and if stacked in that state, it hardly ever gets moistened, but cuts up crumbly and dry, the worst state in which it can be for any purpose. In cutting into an unprotected ridge of soil at the end of 1872, after 60 in. of rain had fallen, it was found that the moisture had hardly penetrated farther than the outer crust—the turves had been cut up dry, being a chance lot that had to be fetched when they could be got. On another occasion a Vine border, or rather part of one, which was furnished with chopped loam in a dry state, was found to be still in almost the same condition a foot from the surface at the end of the season, and that led to an explanation regarding persistent attacks of red spider upon the Vines growing in that portion of the border. It had been copiously watered like the rest of the border, but it had not absorbed the moisture to the same extent; and, in order to insure this, furrows were drawn and holes dibbled all over the surface, and filled with water two or three times a day for a week or more. Loam is not so bad as peat, however, for when the latter gets too dry the water runs through it like a sieve. For these reasons it is preferable to stack the turves when they are tolerably moist. They will drain and get drier, but not wetter, though stacked out-of-doors, if formed with a good sharp ridge at the top like a haystack, and smoothed with a spade, so as to throw off the water. Except for border making and similar purposes, turf should be stored for one year before it is used, or at least until such time as the roots of Grass are killed; but after that the sooner it is used the better, as decomposition goes on rapidly, and in two years' time the fibre on which the value of turf chiefly depends is generally quite gone, and nothing but a fine mealy soil left, good enough for ordinary purposes, but apt to run into a dense impervious mass when used by itself. Of course, the character of the compost, after lying awhile, depends upon the way in which the turves were taken up. If they be pared off more than 2 in. or 3 in. thick, they are sure, unless the pasture be old and

deep, to have a quantity of superfluous earth and stones attached to them, which considerably reduces the amount of vegetable fibre when the compost comes to be chopped up for use; besides, as there are usually strong objections entertained by proprietors to having their parks stripped of the sward, it is not advisable, particularly on shallow soils, to take any more earth than is required. When the turf only is taken, no damage worth mentioning is done, except the eyesore created for the time; but a few loads of garden refuse scattered over the ground, harrowed in, and a few Grass seeds sown upon it, will soon remedy matters.

Artificial Loams.

With regard to preparing loam for potting purposes, an eminent authority in such matters has said that those soils in which the different constituents that compose them are most intimately blended and mixed are the best for plants, chiefly because their food is everywhere readily accessible. No doubt there is truth in this, and experience bears out the statement; but cultivators do not act upon this principle as a rule, for what are called lumpy or turfy composts, which are really not mixed at all, are preferred by them, and it is easy enough to pick out the different materials, such as loam, peat, and leaf-mould with the hand. The value of such composts depends not more upon their mechanical than their chemical combination, and, to promote this, a thorough disintegrating and mixing of all the different substances are necessary. On this principle it is practical enough to manufacture what may be called an artificial loam, and the suggestion may be worth the notice of those who usually have not command of turf from pasture lands. Very heavy loams, or even clay, if allowed to become tolerably dry, may be broken up into fine particles with the back of a spade—or frost will accomplish the same end—and if, when in this condition, an equal quantity of river sand, and one-third or more of finely-reduced leaf-mould or tufted horse-dropping, be added to it, and all thoroughly mixed up together, a compost equal to, and not unlike, good loam will be the result. I have tried such composts, and would not venture to say that they were inferior in any respect to those composed of the usual material, *i. e.*, turfy loam, leaf-mould, and other matters. No one need be short of a suitable compost for potting purposes who has clay for a staple, and can find sufficient sand and thoroughly decayed vegetable mould, whether from Grass, leaves, or litter, to mix with it. The common soil of the garden is the only loam which many can procure, and with such material at their disposal they need not complain. To get it in good condition they should obtain it from a quarter that has been rough-dug and exposed to the frosts, which reduce the most tenacious clods to a fine meal, and it may then be shovelled up in that condition very dry and stored in the shed, when it will always be fit for use. Such a soil, with the usual additions in the shape of manure, sand, and leaf-mould, according to its texture, may be employed without any hesitation for most greenhouse and stove plants that require loam. All soils which have a tendency to settle down into the consistency of putty—and even turfy loams, if heavy, do this eventually—are unfit for plants alone, but add sand in sufficient quantity, and their tenacity is broken up, and you can almost do anything with them. The root action of plants is yet a comparative mystery to us, and cultivators have been, perhaps, a little too dogmatic on the subject of soils, and too particular, thereby engendering a timidity among the half-experienced, which has no doubt, in many instances, been an obstacle to progress, for people do not attempt those things, as a rule, which they are taught to believe they have not the means of accomplishing. There is little doubt that plants are distinctly affected by the character of the soil in which they grow, and particularly by its texture, whether it be hard or soft; but experience seems to prove that any wholesome soil, freely pervious to air and moisture, and containing the necessary elements of plant food in an accessible form, is a perfectly suitable root medium, whether prepared from turfy loam and peat, or more simple and easily procurable materials.—CHERR.

Fruit Trees and Roses in Dorset.—I paid a visit the other day to my old friend Mr. Raddlyffe, at Okford-Fitzpaine, and was much struck with the beauty of the foliage and total absence of blister on over 116 Peach and Nectarine trees that I found in his garden. The situation is much exposed, and the wind was blowing bitterly from the north-east. There is not a fall crop, but a good sprinkling, and I do not know that I ever saw trees in such fine condition. Mr. Raddlyffe's Roses, his other hobby, have been much injured by the severe weather. Many have been cut down to the ground; but many more sheltered were forward in bud, and in good condition. He expects to have 1000 in fine bloom by June 12; the others, amounting to some 1500, will be later.—W. MARRIOTT, *Down House, Blandford.*

SOCIETIES AND EXHIBITIONS.

ROYAL AQUARIUM FLOWER SHOW.

MAY 16 & 17.

This was undoubtedly the most attractive flower show which we have had this season, and the arrangements were all that could be desired. Most lovely were the groups of Roses sent for competition, and especially the fresh and floriferous specimens contributed by Mr. Charles Turner and Messrs. Paul & Son, of Cheshunt. Than those from Mr. Turner we have never seen more beautiful specimens, every flower and leaf of which were as near perfection as possible; Mr. Paul's, being a little earlier, were just a trifle past their best. Among amateur growers, Mr. Ellis and Mr. Moorman had well-grown collections. Messrs. Jackman & Sons, of Woking, showed a choice group of specimen Clematises, including some of their new varieties, and select groups of fine-foliaged plants came from Mr. W. Bull and Mr. B. S. Williams, while Messrs. Cutbush & Sons and Mr. A. Ratty furnished some attractive groups of greenhouse Azaleas. Hardy flowers were well represented by collections from several exhibitors, and of Orchids there were good collections from Mr. B. S. Williams, Messrs. Rollisson, and Mr. J. Ward.

First-class Certificates.—These were awarded to the following new plants and florists' flowers:—

Azalea Jean Vervane (Turner, Slough).—This is a very pretty variety, the flowers of which are salmon-rose in colour, edged with white. It is evidently a free-blooming kind, and one which will make a useful decorative plant.

Azalea Flambeau (Turner).—This has vivid crimson flowers and a compact habit; it is also a free-growing and a profuse-blooming variety.

H. P. Rose John Stuart Mill (C. Turner).—A bright red Rose, large and full, and good in form and substance. It has frequently been certificated before.

H. P. Rose J. B. M. Camm (C. Turner).—A bright rosy-pink flower, very large and full, but of special interest, on account of its rich, full fragrance, which is similar to that of the old Provence Rose.

Tea Rose Jean Ducher (C. Turner).—This is similar in form to Gloire de Dijon, but much deeper in colour. It is its most desirable variety, and well deserves culture.

Aralia elegantissima (W. Bull, Chelsea).—A graceful stove shrub, having digitate serrate leaflets of a dark bronzy-green colour, margined with a greenish red. It forms an elegant table plant, and will be useful for all kinds of decorative purposes.

Pritchardia grandis (W. Bull).—One of the most stately and distinct of all Palms, having large, dark-green, fan-shaped leaves, borne on stout, erect petioles. It has previously been certificated, and would soon become a favourite were it more plentiful than it is.

Kentia Mooreana (W. Bull).—A robust and graceful stove Palm, having recurved pinnate foliage of a deep green colour, borne on stout arching petioles. It succeeds well in an ordinary plant stove, and is in all respects a very desirable plant.

Dracæna Goldieana (W. Bull).—Of all Dracænas this is the most distinct, having ovate acuminate leaves of a dark green colour, striped, or rather barred with silvery-grey. It has previously been certificated, and is well deserving of culture.

D. Rex (W. Bull).—This and the following are distinct varieties belonging to the ordinary coloured-leaved section, and both are well worthy of culture for decorative purposes.

D. triumphans (W. Bull).

Katakidozamia Hopei (W. Bull).—A robust and handsome Cycad, having a scaly stem and long arching leaves, which are very regularly pinnate. It is a welcome addition to a group of handsome decorative plants now rapidly rising in popular favour, and well deserves attention.

Pyrethrum aureum laciniatum (Osborn & Sons, Fulham).—This is a useful addition to golden-leaved carpet bedding plants, and an improvement on the old Golden Feather, inasmuch as it is more elegantly cut into slender segments, the colour being a clear soft yellow.

Clematis Princess of Wales (Jackman, Woking).—This is in the way of Lucy Lemoine, but is a little improvement on that variety; it has large double white flowers, and is well deserving of culture.

Clematis Countess of Lovelace (Jackman).—This is a large double-flowered variety, the segments of which are a rich purplish-lilac colour. It is the best double variety in the whole group.

Trichomanes Bancroftii (Rollisson & Sons, Tooting).—A fresh green stove filmy Fern, having finely divided dark green fronds, forming tufts only an inch or two in height. It is well worth careful culture.

Aralia Veitchii gracillima (Rollisson & Sons).—This is a most elegant form of the now well-known type, from which it differs in having more slender leaflets of a pale grey colour elegantly crisped along their margins. As a table plant or for ordinary decorative purposes it well deserves attention.

Woodwardia radicans cristata (B. S. Williams, Holloway).—A strong-growing Fern, which differs from the type in having the apex of the fronds and the principal divisions regularly crested. It will afford variety in a collection of cool house Ferns.

Polystichum lepidocaulon (B. S. Williams).—A distinct and handsome species, the fronds of which are simply pinnate, the end of the rachis being prolonged in a curious proliferous manner.

Zamia intermedia (B. S. Williams).—A graceful and fresh green cycad, having a brown scaly trunk, whence rises the arched pinnate foliage the whole forming an elegant vasiform plant.

Araucaria Goldieana (B. S. Williams).—A graceful Conifer, with bright green foliage, and one likely to be useful as a decorative plant for the conservatory.

Primula cortusoides maxima (R. Dean, Ealing).—A strong-growing Primrose, which bears trusses of rosy-white flowers on a tall and slender scape. It is quite distinct from all others, and will prove very useful for the rock or pot culture, or for ordinary decorative purposes.

Roses.—To the general excellence of those we have already alluded. In Mr. Turner's collection we remarked examples of Duke of Edinburgh, a vivid crimson-scarlet variety; Madame T. Levet, a full bright rose; Juno, pale rose; Edward Morron, a large, full, rosy variety, flushed with salmon; Madame Victor Verdier, vivid crimson; Paul Perras, a wonderfully fine specimen; Beauty of Waltham, a crimson-purple kind; Celine Forrester, a lemon-yellow Tea; Madame de St. Joseph, a delicate creamy-white Tea-scented variety, with a salmon centre; Victor Verdier, a bright grey rose, the backs of the petals being silvery-lilac; Marginal Vaillant, a crimson-purple variety, very full; and Anna Alexieff, a delicate rosy variety, of good form and habit. Taken as a whole, this collection was as near perfection as possible. Messrs. Paul & Son, of the Old Nurseries, Cheshunt, also showed a beautiful group, in which we noticed Horace Vermet, a deep crimson-purple flower; Anna Alexieff, Juno, Celine Forrester, Madame Levet, and the following, which were not in the first-named group, viz., Princess Mary of Cambridge, a cupped pale rosy flower; Charles Lawson, a full and brilliant rosy variety; Camille Bernardin, a well-formed rosy-crimson kind, and Marie-Basmann, a distinct kind, crimson-purple, and one of the best varieties in the class to which it belongs. Among collections of 20 kinds, in 8-inch pots, Messrs. Paul had the best group, Mr. Turner being second. Messrs. W. Paul and Son, of Waltham Cross, showed a miscellaneous group of Roses in pots, and also some fine collections of cut flowers, tastefully arranged on fresh green Moss, in large circular baskets. These, being backed by a row of Orchids and Palms, and fringed along the front with Isoplepis, formed one of the most attractive arrangements in the show. In the class for 24 cut Roses, Messrs. Paul and Son, of Cheshunt, and Mr. Charles Turner, had excellent stands.

Hardy Flowers.—Of these some charming collections were shown, in which we remarked the following, viz., Erigeron multiflorum, a glossy-leaved plant, having large, white, Daisy-like flowers; Carex argenteus, an elegant variegated variety; many beautiful varieties of Trollius, and Anemone sylvestris, with Snowdrop-like buds, and pure white flowers. In Mr. Parker's collection we noted fine masses of Solomon's Seal; Phlox Nelsoni, a large and open variety, of a rosy violet, spotted with white, with numerous rich purple flowers, and the sky-blue *I. floridula*. The delicate rosy *Spiræa palmata*, and its white-flowered *S. japonica*, were represented by two handsome specimens. A pot of the lilac and white-flowered *Eriopeton reniforme* was much admired, as were also specimens of *Pœonia uniflora*; *P. tenuifolia*, and the deep blue-flowered *Lithospermum prostratum*; we also observed a brilliant mass of the scarlet *Anemone fulgens*, and with it were associated large clumps of white Daisies and *Iberis garretiana*, *Pœst's Narcissus*, and a very fine plant of *Orchis foliosa*. In the class for cut flowers Mr. Parker had the most effective group; it consisted of *Scillas*, *Bluebells*, *Tulips*, *Peonies*, blue and purple *Iris*, *Spiræa japonica*, *Alyssum orientale*, *Iberis*, *Trollius asiaticus*, and two attractive potfalls of the snow-white *Aponogon tenastachyon*. Mr. Roberts, gardener at Peterborough House, Fulham, also had a choice group, as had likewise Mr. R. Dean. Alpine auriculas came from Mr. C. Turner, and Mr. R. Dean, Mr. Turner, and the Rev. H. H. Dombain, also sent groups of show varieties.

Fine-foliaged Plants.—Of these Mr. Bull showed one of the best groups perhaps ever seen; among other plants it contained *Dracæna Goldieana*, a kind with zebra-striped leaves not unlike those of *Phaius*; *Schizanthus*, and *Croton spirale*, with dark bronzy-green coloured foliage, every leaf being twisted like a corkscrew; *Adiantum gracillimum*, a beautiful Fern, to which we have frequently alluded in terms of praise; *Pandanus Veitchii*, in fine condition; and *Croton volutum*, a kind with curled ram's-horn-like leaves. The same collection also contained a fine plant of the golden-blotched *O. majesticum*; *Pritchardia grandis*, one of the rarest and noblest of all Palms; *Paulinia thalictrofolia*, with delicately cut Fern-like foliage; *Phyllostenium Lindeni*, a distinct and effective large-leaved kind, with ivory-white veins; *Kentia Mooreana*, a robust and graceful decorative Palm; and a fine specimen of *Euphorbia peltata* Vrouin. Mr. B. S. Williams had a well-grown group, in which we noted examples of *Adiantum gracillimum*, *Croton Wisemannii*, *Gleichenia rupestris glaucescens*, one of the rarest and most elegant of Ferns; *Maranta Makoyana*, and *Linden's Phyllostenium*, backed up by some graceful Ferns, Palms, and Pandanus.

Table Plants.—Nearly all the exhibits in this class were above mediocrity, the best being sent by Mr. W. Bull; in this we remarked elegant little specimens of *Aralia leptophylla*, *Croton spirale*, *Pandanus Veitchii*, *Geonoma gracilis*, one of the most elegant of all dwarf Palms; *Aralia elegantissima*, a kind with slender pedate leaflets, coarsely serrated, and of a dark bronzy colour; *Croton majesticum*, *Dracæna amabilis*, *Panax excelsa*, a kind with elegantly-fringed, pinnate foliage; *Dracæna Cooperi*, variegated *Cyperus*, and the elegant fan-leaved *Thunbergia argentea*. Messrs. Rollisson and Sons, who were second, showed good plants of *Aralia Veitchii*, *Cocos Weddelliana*, *Croton Wisemannii*, and *Dracæna gracilis*.

Fruit.—From Mr. Earley, of Valentines, Ilford, came a very good collection of Late Apples, the varieties being Red Beefings, Cluster Golden

Pippin, French Crab, Dumelow's Seedling, King of the Pippins, Mothe-Pippin, Dredge's Fame, Five-crown or London Pippin, Golden Russet and others; from the same exhibitor also came Black Worcester and Cattilae Pears, evidently in good condition.

A list of the prizes awarded on the occasion will be found in our advertising columns.

ROYAL HORTICULTURAL SOCIETY.

MAY 17TH.

At this meeting Messrs. Veitch & Sons showed a beautiful group of rare Orchids, to which a Davis medal was unanimously awarded. In this group one specimen, a single one of *Odontoglossum novium* bore between twenty and thirty fine spikes of slender-petaled purplish-spotted flowers, and to this, as an example of superior culture, a gold Banksian medal was awarded. Sir Trevor Lawrence also contributed a well-grown group of Orchids, including a vigorous plant of *Masdevalla Harryana* deserves notice, being not only a distinct variety, but also one which had evidently received the most careful culture. In the same group was a form of *Acerides (falcatum) Larpentae*, with buff-coloured sepals and petals, described more fully below. Mr. Ollerhead, gardener to Sir H. Peek, Bart., furnished one of the finest clusters of Dwarf Plantain (*Musa Cavendishii*) which we have yet seen, its weight being considerably over 90 lbs. Mrs. Lloyd Wynne sent cut blooms of the lovely scarlet-flowered *Embothrium coccineum*, a shrub which is perfectly hardy in sheltered positions, at least in the more southern parts of the country.

First Class Certificates.—These were awarded to the following new and rare plants:

***Boronia elatior* (Veitch & Son).**—A very slender and graceful Australian greenhouse plant, bearing a profusion of bright carmine flowers and buds among fresh green finely cut foliage. It promises to become a decorative plant of the highest possible value, and its elegant sprays of foliage and flowers seem well adapted for cuttings.

***Cypripedium siliigerum* (Veitch & Son).**—This is a robust hybrid, a cross between *C. barbatum* and *C. levigatum*, and has broad, glossy, bright green leaves, with indications of the dark markings of *C. barbatum*. The flowers are solitary and larger than those of any other hybrid Lady's slipper with which we are acquainted. The petals resemble those of *C. Dayii*, but have a few glossy warts on the upper margin; the sepals are greenish-white striped with purple, the lip being of a uniform brown tint. It is very distinct and effective.

***Azalea indica Jean Vervaeke* (Veitch & Son).**—This is a variety possessing good form and substance, the flowers being of a bright rosy-salmon colour margined with white. It is quite distinct, and will be found valuable either for decorative purposes or for exhibition.

***Malva Veitchii gracillima* (Veitch & Son).**—A very slender and desirable form of the now well-known type.

***Clematis lanuginosa violacea* (C. Noble, Sunningdale).**—This is a robust variety with large leathery dark-green somewhat glossy ternate foliage, and elegantly frilled six-rayed flowers, each of which measures 6 in. in diameter, and is of a dark satiny-blue colour, faintly flushed with claret down the centre of each petal. As it belongs to a very hardy group, and is quite distinct in colour from the old *C. lanuginosa*, it will doubtless prove to be a valuable hardy garden flower.

Double-flowered *Cineraria King Alphonso* (E. G. Henderson & Son).—This is a dwarf dense-branched plant, bearing bright rosy flowers 1 in. in diameter, and as double as those of the purple-flowered *Senecio Jacobaea*, which indeed they closely resemble in colour and general appearance. As the flowers last longer than those of the single varieties it well deserves attention as a decorative plant.

***Acerides Mendelii* (Sir T. Lawrence).**—This is a very distinct form of the very variable (*Acerides Larpentae*), or, as it is more frequently called in gardens, *A. falcatum*, from which it differs in having buff-coloured sepals and petals instead of white ones. It is quite distinct as a garden plant, and were it and its ally—*A. crassifolium*—more plentiful, both would be desirable plants in the most select collection of Orchids.

Variegated Broccoli (Harley).—A dwarf compact form of common Broccoli in which the centre of the leaf is of the purest milk white margined with green. If it can be perpetuated by means of seeds it will be useful as a decorative plant.

Orchids and other Plants.—Messrs. Veitch & Sons showed a choice and effective group of rare Orchids, *Falms*, hybrid greenhouse Rhododendrons, and other decorative plants. Among Orchids we remarked four vigorous plants of the delicate rosy-flowered *Odontoglossum vexillarium*, all differing one from another in the shape of flower or in brightness of colouring. The largest plant bore twenty-seven flowers on six spikes. One pale variety of exquisite form had radiate-rosy markings at the base of the lip, and was altogether one of the most chaste and beautiful of the whole group. A strong plant of the golden-flowered *Oncidium Marshallianum* bore twenty-six flowers on a long branched spike. A vigorous plant of *Cypripedium Donnellii* was furnished with four flowers on two spikes, the individual blooms resembling those of *C. caudatum*, but in colour more glossy brown. Its parents were *C. caudatum* and *C. Pearcei*, and in general habit of growth it resembles the last-named, but it is much more robust. A specimen of *Dendrobium Bensoniae* bore upwards of forty white yellow crimson-blotched flowers on two erect grey pseudo-bulbs. *Laelia Walstenholmie*, a plant having the habit of *L. elegans* and flowers like those of a pale *L. purpurata*, had two spikes, the largest of which bore seven flowers; and on a plant of the soft golden-yellow *Oncidium concolor* we counted

fifteen flowers. Among *Cattleyas* we remarked several good varieties of *C. Mossiae*, and a vigorous specimen of the pale, rosy-petaled carmine-tipped *C. Mendelii* bore three two-flowered spikes. A large pan of the chaste white-flowered *Cypripedium niveum*, from Malaya, was much admired. Its waxy-white flowers contrasting well with the dark green grey-blotched leaves. A plant of the rare *Cypripedium Dayii* bore two fine flowers, and a noble specimen of *Odontoglossum novium* was furnished with twenty or thirty spikes. The rare *Vanda Parishii* bore a strong eight-flowered spike of sweet-scented blossoms; a very large plant of the fox-brush *Aerides (A. Fieldingii)* had five long spikes of rosy-lime flowers; *Dendrobium thysiflorum*, *Epidendrum prismatocarpum*, and *Angulosa Ruckeri*, were also well represented. Sir Trevor Lawrence showed several very beautiful and well-grown Orchids, including a form of *Acerides Larpentae*, having buff sepals and petals, named *A. Mendelii*, to which, as will be seen, a certificate was awarded. A very fine variety of *Masdevalla*, in splendid health and vigour, bore twelve large and richly-coloured flowers, the colour being a sanguineous carmine; a plant of the pretty little yellow-flowered *Promenaea citrina* bore seven or eight short-stalked flowers amongst its pale glaucous green leaves; a plant of *Dendrobium cariniferum* bore twelve glossy, whitish-petaled flowers, the lip being of a dull Roman-red colour. From Messrs. E. G. Henderson & Sons, Wellington Road, St. John's Wood, came an interesting group of dwarf-habited, large-flowered Mimuli. These formed compact little plants from 2 in. to 3 in. in height, bearing pale or golden-yellow flowers fully 2 in. in diameter, and variously spotted and blotched with crimson of different shades. These *Liliputians*, which are very distinct and beautiful, are greatly in advance of any other seedling Mimuli which we have hitherto seen. The same exhibitors also furnished two double-flowered *Cinerarias*, one having dark purplish-blue and the other bright rosy flowers. Mr. Green, Botanical Nursery, Holmesdale Road, Reigate, showed a fine mass of a dwarf pale-golden-flowered Iris, named *I. pumila lutescens elegans*, a kind which appears to be very floriferous, and well deserving of culture.

Fruit and Vegetables.—Messrs. Harrison & Son, of Leicester, contributed examples of their new Apple, Annie Elizabeth, in an excellent state of preservation; examples of a seedling Apple also came from Mr. W. H. Bland, of the Old Nurseries, Fordham, Cambridge-shire; Mr. Batters, gardener to Mrs. Willis Fleming, of Chilworth Manor, Romsey, Hampshire, showed four dishes of vegetables, amongst which were a dish of McLean's Little Gem Pea, Early Long-pod Broad Bean, Moore's Cream Vegetable Marrow, and some excellent Walnut-leaved Potatoes. The seed of these was planted in 8-in. pots in February and the crop was ready for use the first week in April. These had all been grown placed on the shelf of a cool house. Mr. Potter showed a fine lot of Telegraph Cucumbers; and specimens of Cucumbers and Melons affected with Cucumberspot, from Mr. Sage. The fruits were said to exude pure pectic acid. Virgin soil was stated to be the only sure preventive, and Mr. Berkeley recommended the use of soil which is washed down chalk gullies by heavy rains.

NOTES AND QUESTIONS—VARIOUS.

The late Mr. Richard Heady's Tulip Sale.—The stock of Tulips and other florists' flowers that belonged to the late Mr. Richard Heady is to be sold by auction at Stapleford on Tuesday, May 23. Amongst the Tulips will be found the celebrated John Linton, Sarah Heady, John Thornley, and other fine kinds, and, besides the named varieties, there will be sold a large collection of valuable breeders. This sale affords a good opportunity for possessing a stock of the best kinds of Tulips and Ranunculuses.

Flower Gardens in Churchyards.—Dr. Tristram, the Chancellor of the Diocese of London, has just settled the terms of a faculty, which will be forthwith issued, to convert the churchyard of St. George's-in-the-Bast into a Flower Garden. We again hope that annual decorations merely will not be the only object in view in taking advantage of this decision, but that suitable trees will be planted.

Campanula pulka.—I am obliged to "Scholastica" (see p. 408) for directing my attention more particularly to this little *Alpine Bellflower*. Since reading his remarks I have ascertained that the plant I saw on the flank of the Schlern, is not, as stated in my letter from the Tyrol, *C. pulka*, but *C. Scheuchzeri*, which is a totally distinct plant from *C. Moretiana*.—W. DREXLER.

A Double Wild Primrose.—A very large and effective double-flowered form of the common yellow Primrose has been sent to us by the Hon. and Rev. J. T. Boscawen, who found it in an old Oak wood near Lamorna, in Cornwall, and fully a mile from any house, whence it is inferred that it is not a garden straggler. Its flowers are bolder than those of any double yellow Primrose with which we are acquainted. They are borne on stout scapes 6 in. in length, and the variety is evidently very vigorous, judging from its foliage, it may prove to be a very desirable plant for decorative purposes.

The Virginian Lungwort.—I so rarely see *Pulmonaria virginica* in a really thriving state that I write to say I had that pleasure the other day. The plant was nearly 2 ft. high, and full of lovely flowers. It grew in an open position, in very sandy and deep soil. It is an old favourite that I hope to see more frequently henceforward. It probably would thrive admirably on the margin of a Rhododendron clump, the soil of these being very suitable to it.—K.

Plant Collecting in the Tyrol.—May I suggest to "Wanderer" (see p. 301) that the much branched annual with whorls of scarlet fruit that he found, and of which he did not know the name, might possibly be the Strawberry Blite, or Strawberry Spinach, *Blitum capitatum*.—G. F.

Scutellaria macrantha.—"W. J." (see p. 428) is quite right in his remarks respecting this plant. It was *S. cordifolia*, not *macrantha*, which I intended to have named.—J. S.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

NEWLY IMPORTED ORCHIDS.

SCARCELY a week passes during the warmer months of the year in which consignments of Orchids are not received in this country, and as much misapprehension exists with respect to their treatment, it may be well to lay down some definite rules by means of which the destruction of many beautiful plants which cost much patience and care to collect and convey to this country, may, to some extent at least, be avoided. One of the greatest and most common mistakes with respect to the treatment of newly imported Orchids, is to lay them under the stages of the Orchid-house for a considerable time before potting them; in some cases water is freely poured over them from a rosed watering-pot, and that even while the plants have the stagnant moisture from the floor to contend with—frequently aggravated by drip from the plants on the stages above. Such treatment while Orchids are weak from traveling only tends to make matters worse, and it is not surprising that when taken up for potting only the strongest remain alive, and even these are in a worse condition than when they arrived; another kind of treatment almost as mischievous is to pot the newly imported plants immediately on receiving them, putting them in a warm house to grow. If the plants arrive in very good condition and during their proper growing season the consequences may not be so bad, but in any other case failure is sure to be the result. All newly imported Orchids are more or less emaciated, a condition brought on gradually during the journey, and any attempt to suddenly make them plump only excites the impaired cellular tissues in places and utterly destroys them in others; consequently, we often see newly imported plants so treated with parts of the pseudo-bulbs or leaves looking healthy and green, and the other parts indented, black, and decayed; such plants are unfit to produce sound, vigorous growth; imported plants having become gradually emaciated should be as gradually brought into their usual condition, in order that each cell may slowly fill out until the whole are in proper condition. Orchids forwarded to this country have had enough of ill-treatment which could not be avoided; therefore, immediately on their arrival they should be placed under comfortable circumstances, the treatment to which they are subjected being in accordance with the time of year, the condition in which they arrive, and the state in which the last-made growth happens to be. If some of the plants have not started, and others have made weakly growth on the journey, in unpacking the two should be kept separate, and afterwards managed according to their respective wants. Orchids travel best when they are gathered just as the growth is matured or within such a period afterwards as will allow of their reaching this country before their natural growing season has commenced. Plants so gathered are often received without much injury and with the young growth not started but ready to start as soon as the plants have been got into a sufficiently healthy condition.

On receiving plants of this description they should be taken out carefully one at a time, sponged all over with tepid water, and placed on Sphagnum Moss on a stage, in a cool, shady house (about 60°, or as near that as possible), repeating the sponging each morning for three or four days, when, if the plants be *Cattleyas*, *Lælias*, *Odontoglossums*, *Oncidiums*, or similar subjects usually grown in pots, they should be placed into the smallest possible pots, and returned to the place in the house which they occupied before they were potted. The pots for receiving the plants should be prepared with rough crocks, after which the roots should be put in, holding the plant level with the rim of the pot, filling up with finer crocks, and steadying it, if necessary, with a stick, but no Moss or peat should as yet be used. The crocks in which the plants are placed should be watered with a spouted watering pot:

sparingly at first, but when the plants begin to grow water may be given freely in the same way. As soon as the young growths and roots are fairly started, the plants should be placed in a warmer house, and in a few days potted in the ordinary way, or put into baskets, which should be small in proportion to the size of the plant; freshly imported *Dendrobiums*, unless of too large growth, should always be put into baskets, or on blocks. The difficulty, however, experienced in obtaining many varieties of Orchids, often obliges collectors to gather them when they are making new growth, or so near the growing season that they start into weakly growth during the journey, and in such cases they are more difficult to manage. Many plants sent under such conditions will be found to have lost their leading growth, and will have to depend on the back eyes, and the young growths of others will be so weak and blanched as to require the greatest care to prevent them from rotting; it is highly important, too, that plants received under such conditions should not be allowed to get wet, and therefore they must not be sponged for fear of the moisture getting among the frail growths. They should be handled very carefully, taken out one at a time, and suspended head downwards in a shady house, the temperature of which is that previously recommended, for ten days or a fortnight without having any water given them; a moist atmosphere and a regular heat should, however, be kept up, but it must not be allowed to range high at any time, or in place of reviving the plants it will still further exhaust them. During the time they are suspended, they should be looked over daily, and their positions altered, in order to prevent them from becoming drawn, and any that may be found with their young growth beginning to turn up towards the light should at once be hung the right way up, or placed on blocks. At the expiration of the time stated, the plants will have become somewhat acclimatised, and may be placed in pots or fastened on blocks, and treated in the manner previously described; but the great object should be to prevent the water from getting into the new growth. Should the temperature of the house not be easily kept down, instead of suspending the plants, it will be better to place them on living but not wet Sphagnum Moss, on a stage in the coolest part of the house, taking the same care as before with regard to water.

A good block for Orchids, and one that does not easily decay, is made by cutting some rough cork into pieces from 4 in. to 6 in. in diameter, boring a hole in each side and attaching to it a stout copper wire; the wire should be brought up to a point in the middle and turned round, so as to form a hook by which the block may be suspended, after the manner of the ordinary basket used for Orchids. When arranged in this way the cork hangs horizontally, the concave side being up, and it retains moisture much better than blocks hung perpendicularly, besides being more suitable for the growth of the plants; the latter should be fastened to the blocks with fine copper wire, using as little of it as possible, and placing a little Sphagnum Moss here and there under the wire to prevent it from pressing on the roots. *Aerides*, *Angræcums*, *Saccobulbiums*, *Phalænopsis*, and all Orchids of similar growth should be unpacked, sponged, and suspended head downwards in a moist, cool house for ten days or a fortnight, sponging them over each morning during that time, after which the large growing varieties should be fixed in pots with crocks and charcoal, and firmly fastened to a stick, but no Sphagnum should be used until the plants begin to root. *Phalænopsis* and smaller growing kinds should be fastened on blocks or in baskets with crocks and charcoal; the crocks should be watered from time to time with a spouted watering-pot until the plants begin to root and grow, when they should be placed in a warmer house and top-dressed with Sphagnum Moss. Newly imported Orchids should never be syringed, but attention should be paid to the maintenance of a low genial temperature and moist atmosphere by throwing water on the floor and under the stages, and the plants should be treated, after the first fortnight or three weeks, in much the same way as established plants with respect to heat, &c.; that is to say, if the growing season of the plants imported have not arrived, they must be kept cool until they grow, but if they arrive at a time when they should start into growth they should be gradually prepared for being placed in the warmer house at once. Some recommend cutting away the dead portions of

the leaves and the dead roots before placing the plants in pots, but, in my opinion, it is not good practice to do so, as it admits air into the inner structure of the plants at a time when they are inactive; it is better to leave them as they are, and afterwards remove any portion of them that seemed to be dying back. It is natural for Orchids, even when established, and also in their native habitats, to lose some of their back bulbs, but they nourish the plant when left on until they are quite dry. The *Odontoglossums* of the *Alexandræ* class should never have the old bulbs cut off; one may often see plants of this class push vigorously from the rhizome beneath the dead bulbs of an apparently dead plant, and afterwards make sound plants; whereas, if the dead bulbs had been removed, the whole would have been lost. Evergreen terrestrial Orchids from warm countries should be potted immediately on their arrival, and placed in a cool house for a few days without having water given them, after which they should be put in a warm house and treated like other plants of the same kind. Deciduous terrestrial Orchids from warm countries should be potted immediately on their arrival; they should be kept in a cool house, and but sparingly watered until they begin to grow, when they should be placed in a warm house. In winter and spring Orchids are often received which have been exposed to too much cold on the journey, sometimes being even nipped with frost, and this kind of importation is perhaps the worst of all with which to deal, for tropical Orchids, either established or imported, which have been subjected to anything approaching frost, if they ever get over it, remain sickly and unsightly for years. I have seen Orchids which have been touched by frost on the journey brought round by being immersed in cold water for an hour or so when unpacked, afterwards sponging them almost dry, and placing them in a cold house on Sphagnum Moss; the immersion and drying should be repeated each day for three or four days, and the plants should be left in the cold house until they exhibit signs of renewed growth, when they may be treated as importations received in good condition. The great aim in the resuscitation of newly-imported Orchids should be to place the plants from whatever part they may come at first in such a low general temperature and moist atmosphere as shall necessitate giving little or no water, and to keep them cool and rather dry until both top and roots begin to start into growth.

JAMES O'BRIEN.

Plant Exchanges.—A pamphlet was put into my hands the other day by a botanical friend, entitled, "Rules for the London Botanical Exchange Club," that is to say, a club meant to facilitate the exchange of dried specimens of plants. My friend, however, on showing it to me, said—Why cannot something of this sort be done with living plants? And the idea seemed to me to be so good that I venture to trouble you with a few lines about it. Any one who is trying to form a collection of living plants must know how often he has more of some rare and good plant than perhaps he cares for, while another person would be glad to give in exchange for it what he would prize very highly. Indeed, exchanges among the lovers of rare and beautiful plants are not unrequited now. My object, then, in writing this letter is to ask if any system could be introduced like that alluded to above by which exchanges could be made more easy than they now are, and those who are pursuing the same end could be brought into contact with each other. Only a small annual subscription would be required, as in the case of the London Botanical Exchange Club. The greatest difficulty would be (as in its case) in finding a secretary; but might not this office be held in turn by different members? It would not then, I think, be so very burdensome. Lists of desiderata could be made out, and there would thus be very great assistance in forming collections. At all events, if you think it worth while, I shall be glad if the idea can be ventilated in your columns. Nurserymen would have nothing to fear from it, for it never could take effect on a large scale, and it would be only amongst those who already have some rare and beautiful plants which they offer to others. I think it would, from one point of view, even tend to the purchase of rare and expensive plants. One could buy them with a view to exchanges after a little time, when they have been multiplied.—PROGRESS. [We believe all attempts to establish a system of plant exchanges in this country have hitherto failed.]

Rheum officinale.—Any of our readers who may be interested in the history and cultivation of the Official Rhubarb, will find an exhaustive article on the subject by Professor Flückiger, in the new volume of the "Repertorium für Pharmacie."

THE BEST GARDEN MOUSE-TRAP.

MORE than twenty years ago I managed a place where our kitchen garden was partly surrounded by Beech woods; consequently we were greatly troubled with mice, which made sad havoc with newly-sown Peas and other seeds. The accompanying is a representation of the trap which I employed for their destruction, and which was eminently successful, for we trapped them by hundreds. I instructed our potter to make me a number of glazed pots about the size of a 24-in. pot, but 2 in. or 3 in. deeper. There were four projections on the upper edge, as shown in the sketch, each pair being placed $\frac{1}{2}$ in. apart. The pots were only glazed inside. The rest of the apparatus consisted of a round stick $\frac{3}{4}$ in. in diameter, on the centre of which was fixed a turned wooden roller 3 in. in diameter and $\frac{3}{4}$ in. thick; the round stick, being 5 in. longer than the diameter of the pot, projected $2\frac{1}{2}$ in. over its outside each way. Four or five baits were fastened on the edge of the roller with tin tacks; the baits consisted of either cheese or bacon rind, or garden Beans. Thus baited, the stick was laid between the projections on the rim of the pot, with the roller exactly in the centre. The pots were half-filled with water, and sunk in the soil, so that the stick, when in position, cleared the ground about one-eighth of an inch. A mouse endeavouring to get at the bait has to travel along the stick to the roller, but cannot reach the bait without rising on

A Garden Mouse-trap.

the roller; when it does this the roller revolves, the mouse loses its balance, and is precipitated into the water, leaving the trap ready set for others to follow. The dead mice should be taken out every morning and the roller removed to be replaced in the evening, for birds sometimes dislodge the baits during the day. A little more water must be put in the pots as required. As many as nineteen mice have been drowned in one of these pots in a single night. It is undoubtedly the best mouse-trap for a garden with which I am acquainted.—HENRY A. WOOD, *Willow Lodge, Mitcham.*

Cork Tree-guards v. Hares and Rabbits.—I have hit upon a good expedient for protecting the bark of young trees from the attacks of hares and rabbits, and one which can be readily applied. The material which I use is Virgin Cork, at present so much employed in the construction of Ferneries, and which can be procured in pieces of all shapes and sizes, that can be easily placed round the stems of young trees, and attached in such a way that the attacks of hares and rabbits will be rendered ineffectual. The mischief caused to specimen trees planted near dwelling-houses, in parks, or on lawns by cats and dogs, &c., may also be prevented by the same means. I first fix the pieces in their proper position, and then fasten them together with wire or strong twine, an operation which can be done at a trifling expense; but, of course, such tree protectors might be made to close round the stems, and open and shut by means of hinges.—WILLIAM BAXTER SMITH, *Knowesfield, Uarliste.*

Dovedale Moss (see p. 467).—This plant is doubtless *Saxifraga hypnoides*, or one of its many varieties, as I believe no other kind grows in Derbyshire. The Mossy *Saxifragas* constitute a distinct group, in which there are perhaps fifty to sixty species and varieties, and many of them are eminently beautiful, varying as they do from the silvery grey of *S. pinnatifida* to the emerald green of *S. virescens*. I cannot say more as to their adaptability for covering otherwise naked surfaces, than I said in my last communication to THE GARDEN (see p. 399). Of course they are meant to be permanent; and if the bulb bed has been properly prepared, the planting or lifting of the bulbs becomes an easy matter; besides, a few beds of these help to tone down a blaze of colour in geometrical gardens, and I really wonder that they do not enter largely into the composition of this style of decoration. There is only one answer to be made to this—they are not sufficiently known. As edgings many of them are quite equal to Box, and they will flourish in a great many situations where Box will not grow.—THOMAS WILLIAMS, *Bath Lodge, Ormskirke.*

NOTES OF THE WEEK.

— THE trees in the parks and in Kensington Gardens are now in great beauty, the Hawthorns and Chestnuts being particularly fine. There is a little open lawn with a small Lime tree in its centre, quite near the Rotten Row corner of the gardens, around which there are several charming tree pictures. One Hawthorn is about 40 ft. high. Some of the central unfrequented portions of the park are among the most attractive. Nobody should despair of growing flowering trees in London after seeing Kensington Gardens in their present dress.

— THE Yube Oranges are at this moment the most delicious obtainable in the market, and remarkable for size, delicacy of flesh, and flavour. Every year sees the Orange cultivated in a greater number of localities, and as a consequence we have supplies extending over a longer period of the year than was the case some years ago. It is satisfactory to note such progress in the culture of the most valuable of all fruits.

— THE earliest Cornflower blossoms (*Centaurea Cyanus*) have come in from autumn-sown plants, and very useful they are. The hardy perennial blue Cornflower (*C. montana*), being earlier than the common one, is also sent to the flower markets, but not being quite so good in colour or form, will be little sought for now the true plant has come in. A little seed of this plant should be sown every autumn in gardens where the plant is not allowed to "sow itself," as the flowers are most precious for cutting in early summer.

— VERY fine samples of Broccoli in large quantities come from the neighbourhood of Ponder's End, Enfield. The variety is called Mitchell's Champion of England. It is the best specimen we have seen sent in quantity to the market.

— THE old Turban and other varieties of the Ranunculus, in blossom at this season, are among the few old-fashioned flowers which do not seem to be again coming into general cultivation. Few flowers are, however, more attractive or beautiful, and we hope they will be more cultivated in future.

— BOTH in England and Belgium there are movements on foot promoting memorials to the memory of the late M. Louis Van Houtte. A meeting will be held at South Kensington on Friday, June 2nd, at two p.m., to consider the British memorial.

— THE Brighton Corporation have established a nursery of their own for supplying the gardens of that town with flowers and trees. As the adoption of this plan, if well carried out, cannot fail to help the cause of public gardening in towns, the example is worthy of general adoption.

— THERE are now noble masses of blossom on a plant of *Viburnum macrocephalum* against a wall in the Alpine plant frame ground at Kew. In the same border there is a good plant in flower of the rare and curious *Craspedia Richei*, a plant of the Natural Order Compositae, having rich yellow, globular heads of flower.

— THE markets are now well supplied with the delicate little Carrots grown in the Paris gardens: in fact, Covent Garden in the morning reminds us in places of the neighbourhood of the Halles in Paris, where the streets are half covered with these Carrots in the early mornings. It is much to be desired that the same or a similar system of culture would be adopted near other large cities, as it need hardly be said the conditions of success are not confined to one place.

— THE REV. J. B. NORMAN, of Whitechurch Rectory, Edgware, informs us that he has now, in his collection of Orchids, *Masdevallia Veitchii*, bearing over fifty flowers and buds; *M. ignea*, with sixty flowers; several fine forms of *M. Harryana*, and a plant of *M. trochilus*, bearing several of its rich golden-brown flowers. Of *Cattleya Mossii* there are stated to be upwards of fifty plants in bloom in this select collection, one of which—a plant from the famous Manley Hall collection—is especially beautiful, the flowers being of fine form and substance, and very chastely coloured.

— WE have just received from Marshall P. Wilder, the report of the American Pomological Society for the Session of 1875, a most instructive, well-filled, and well-printed work. Comparing this with anything issued by our Horticultural Society for many years past may serve to show us to what impotent condition our own Society has fallen. The American Pomological Society is a great power, and well organised for good—a most effective collector and distributor of sound knowledge throughout that mighty land. There are various reasons to account for the success of this great Society, but one of the main ones is that it is exclusively composed of men who have their hands and hearts in the work. Here it is too often the rule to make up the governing bodies of such societies

partly or wholly of men who know nothing of the work to be done, but [whose social or other influence gives them predominance. Between these and the feeble body-bodies who are usually to be found connected with societies, these bodies are frequently rendered powerless for healthy action.

— THE REV. J. G. NELSON sends us from Aldborough Rectory a lovely series of seedling Alpine Phloxes (Alpines of the Rocky Mountains, we mean) of varied and beautiful colours. They are mostly varieties of *P. subulata* and *P. setacea*. Some are white, with purple centres, and very chaste and pretty. It is probable that these little mossy Phloxes may one day yield a race as varied and vivid in colour as the tall Phloxes of our gardens. We hope, therefore, Mr. Nelson will perpetuate the more distinct of these seedlings, and that the birth-place of Phlox Nelsoni may also prove that of other precious forms of the mountain Phloxes of America.

— It is to be regretted that the Bird Cherry, now laden with its long bunches of sweet flowers, is not more frequently met with; also that amateurs do not take up such subjects as flowering trees and shrubs instead of allowing the jobbing gardener to plant his universal mixture of Privet, Laurel, &c. Many a small suburban garden might easily show a choice collection of flowering shrubs or low trees where the above subjects now prevail. Even a collection of Lilacs would be better than the invariable monotony that prevails.

— TO MR. W. E. GUMBLETON, of Bolgrove, Queenstown; the Hon. and Rev. J. T. Boscawen, of Lamoran Probus, Cornwall; and Mr. Luscombe, of Combe Royal, Kingsbridge, Devon, we are indebted for flowering specimens of what is, perhaps, the most valuable shrub ever introduced so far as the southern counties of England and Ireland are concerned. We allude to the Fire Bush (*Embothrium coccineum*) introduced by Messrs. Veitch from South America, and now found to be a hardy shrub. It is wholly unique among shrubs, and produces abundantly its large bunches of long vivid scarlet flowers. We propose to figure it in due time in THE GARDEN, as such a brilliant gain for our own gardens deserves to be widely known.

— At a meeting of the Edinburgh Botanical Society, held on the 11th inst., an interesting communication was read from the Rev. D. Landsborough, on experiments in growing several Australian plants and trees in Arran, in the Firth of Clyde, including among others the great Australian Tree Fern and other Tree Ferns, Acacias, and Gum trees. The Blue Gum grew 1½ in the first year, 4 ft. the second, and 6 ft. the third. The *Eucalyptus pendula* also grows well in sheltered situations along the west coast, and Mr. Landsborough expects to see it generally introduced in a few years, when it will form a valuable addition to our evergreen shrubs.

Box in Washington's Garden.—The Box edgings in the garden of Washington, at Mount Vernon, are still in a healthy condition, though over 100 years old. They are well kept and cared for. The estate was named Mount Vernon by Washington, out of respect to Admiral Vernon, who commanded the West India squadron of the English fleet.—"Gardeners' Monthly." [When we saw these edgings in 1870 they were nearly 4 ft. high, but none the less interesting on that account, and we remember admiring the vigorous growth of the Box and its strong and agreeable odour. Washington's garden is a very interesting one, and we hope that its trees and shrubs may be long preserved.]

Names.—It is a pity that three such important products as Coca, the Cocoa of the breakfast-table, and the Cocoa-nut, though completely distinct both botanically and in their properties and uses, should have names so provokingly similar that most people, we believe, are puzzled to say which is which. The Erythroxylon Coca (says "Chambers's Journal") has no connection with the Cocoa tree (*Theobroma Cacao*), which yields the well-known beverage cocoa or chocolate. Equally distinct from both is the Cocoa-nut Palm (*Cocos nucifera*), the fruit of which supplies the inhabitants of many tropical coasts and islands with a great part of their food, and also furnishes the Cocoa-nut oil of commerce. It is the more solid ingredient of this oil, known as Cocoa-nut butter, that is so much used as an unguent, when mixed with a little Olive-oil, to give it softness. Among many changes of nomenclature constantly going on, could nothing be done to remedy the perplexity caused by so many diverse articles being known by names so closely resembling each other?

Rookeries in Wrong Places.—I have a liking for rookeries, and every good feeling towards their inhabitants, but I must confess with sorrow that I am greatly inconvenienced by the rooks continually taking possession of new trees in the most commodious places, such as a much frequented walk, or a bridge over which they build their nests upon the boughs of trees which overhang, which are generally so high that no one can reach them to pull down the nests, and it would be a ruinous cure to cut the limbs of the trees. Perhaps some correspondent may know some means to send rooks from trees where they are not wanted.—O.

TREES AND SHRUBS.

THE MAJOR OAK AT THORESBY PARK.

The annexed illustration, prepared from a photograph, represents a grand type of forest Oak growing at Thoresby Park, Notts. This fine old tree measures, at 2 ft. above the base, 30 ft. in circumference, the smallest girth of the bole being 27 ft. 9 in.; immense buttress roots crop up 2 ft. above the ground and extend outwards for several yards. Although the hollow in the trunk is 6 ft. 6 in. in diameter and about 15 ft. in height, and capable of holding ten or twelve persons, this tree produces a massive head of vigorous foliage every season; the spread of its branches is about 27 yards in diameter, and some of its limbs girth from 8 ft. to 12 ft. The age of this tree is uncertain, but it may, I think, safely be set down at not less than 1000 or 1200 years, and, judging from its vigour at present, it may yet live for several centuries. There are many Oak trees in this country with larger trunks than that of the Major, but I question whether there is another tree with such a noble, well-balanced, massive head, and with such wide-spreading and huge limbs. Thoresby, forming, as it does, part of "Merrie Sherwood," can probably boast of possessing more old Oak trees than any other domain in England; they abound in countless numbers intermixed with wild Birches of varied and beautiful forms, and are, for the most part, short, rough, and burly; many of their trunks are swollen and distorted into all kinds of grotesque shapes, and, notwithstanding that the majority of them are more or less in an advanced state of decay, the immense quantity of young shoots produced by them is surprising; the interior roots are in every case gone—probably many centuries ago—still their trunks, where sufficient vitality is left, are expanding, although decay is going on inwardly. Mr. Jamieson, the wood manager at Thoresby, directed my attention to what he calls his favourite Oak, named "Simon Foster"; it is certainly a remarkable tree, and one which, on account of the rich colouring of the trunk, is quite a study for an artist. I measured its bole, and found it to girth at 2 ft. up, 31 ft. 6 in., and at 6 ft. up, 23 ft. Timber trees of nearly all kinds attain large girths at Thoresby. A Beech, probably the largest in England, at 5 ft. up measured 17 ft. 6 in.; a Birch at 5 ft.; 16 ft.; a Larch at 5 ft., 11 ft.; and I also observed many fine specimens of old Scotch Firs.

GEORGE BERRY.

Longleaf.

A Plea for Trees in London.—"Referring to the paragraph under the heading, 'Flower Gardens in Churchyards,' in the 'Times' a few days ago, I shall be glad if you will allow me to say a word for trees to those who may have to take advantage of the decision mentioned therein. In dealing with open spaces in cities, the first aim should be to make them tree-gardens, and afterwards make what provision the skill or means at the disposal of the governing body may allow as regards floral decoration. A variety of beautiful deciduous trees will thrive in London if carefully planted, and not the least of their good qualities is their taking care of themselves, so that subsequent neglect has little or no harmful effect on them. A very little money spent on well-chosen deciduous Trees gives a noble result in due time, whereas many thousands of pounds are annually spent in London and its suburbs on subjects that are only planted to die, or at most only survive a few years."—"Times."

Embothrium coccineum.—At the last meeting of the Royal Horticultural Society the Rev. M. J. Berkeley exhibited a specimen of this charming plant in flower. It is said to be as hardy as *Berberis Darwinii*, and, if it be so, no good garden should be without it. If I remember rightly, however, some bunches of *Embothrium* were sent to the Horticultural Society's Gardens, South Kensington, a few years ago, for exhibition, from a gentleman's garden in South Devon, and I was under the impression that they had been matted up in winter with great care; therefore, what I want to know is whether the plant is really hardy or not.—F. B. S. (The Hon. and Rev. J. T. Boscaen, writing to us from Lamorran Probus, says—I have a good plant of *Embothrium*, which has been out-of-doors for some years, and it has never been injured by frost, although in an exposed situation—lowest temperature, 16° this year. At Combe Royal, Kingsbridge, South Devon, the *Embothrium* bloom is said to have been sadly injured by the spring frosts. Last year the two principal

specimens of *Embothrium* there were literally a mass of glowing red from top to bottom.]

The Eucalyptus in Algeria.—Its culture in Algeria was commenced on a large scale in 1867. The first plantings have already produced wood that can be utilized in carpentry and wheelwrighting. Planks over 40 ft. long have been cut, showing that after eight years of growth this tree will produce timber of great value and utility. The hygienic qualities of this tree, claimed by writers in other countries, do not appear to have been realized in Algeria. The plantations have had a remarkably thrifty growth, yet no diminution in the cases of malarial fever are noted. The wood is said to be harder than that of any other tree growing in that region, and its production promises much profit.

Cercis canadensis.—I saw a fine old tree of this in flower at the vicarage, St. Glavias, the other day. It is fully 20 ft. in height, and as much, I should think, through, and covered with pink, pea-shaped flowers, which are used by the French Canadians in salads. Patches of bloom appear on the old bare branches 3 or 4 in. across, and look as if they were tacked on; part of the tree has to be propped up. This tree—for it is more than a deciduous shrub—is worthy of being planted by carriage drives and in pleasure grounds much more generally than it is, both on account of its flowers, which come in at a season when outdoor blossoms are most appreciated, and also on account of its leaves, which assume a scarlet hue in autumn. —HENRY MILLS, *Enys, Penryn, Cornwall.*

Evergreens for Damp Situations.—Some two years ago I had some long oblong beds made adjoining a piece of water in our ornamental grounds. These I filled with Ivy; this, however, has turned out a failure, and as the ground lies low, and is close to the water, I presume the situation is too damp for it. I may add, that on digging down we found water within 18 in. of the surface. As I am anxious to clothe these beds with, if possible, an evergreen that will stand the damp situation and yet look ornamental, I shall be much obliged if any of your correspondents could recommend me some subject suitable for the purpose. I am also desirous of covering some ground under trees. We have planted Laurels, but I find that they do not thrive under such circumstances.—A SUBSCRIBER.

Covering for Tree Wounds.—It often happens that, either by intention as in pruning, or by accident, trees are wounded in various ways. A common practice is to cover large wounds with coal-tar, but this is objected to by some as injurious to the tree. Experiments made in the orchards and gardens of the Pomological Institute, at Ruthlengen, in Germany, go to show, however, that its use in covering large wounds is not injurious; but that, on the contrary, a callus readily forms under the tar, on the edges of the wound, and that the wounded part is thus protected from decay. There is, nevertheless, another objection; for if the tar be applied a little too thick, the sun melts it and it runs down on the bark of the tree. This can be obviated by mixing and stirring, and thus incorporating with the tar about three or four times its weight of powdered slate, known as slate flour—the mixture being known as plastic slate, and used for roofing purposes. It is easily applied with an old knife or flat stick, and though it hardens on the surface, it remains soft and elastic underneath. The heat of the sun does not melt it, the coldest winter weather does not cause it to crack, neither does it peel off. The same mixture is also useful for other purposes in the garden. Leaky watering-pots, barrels, pails, shutters, sashes, &c., can be easily repaired with it, and much annoyance and loss of time be thus avoided. It will stick to any surface provided it be not oily, and as it does not harden when kept in a mass, it is always ready for use. A gallon will last for a long time.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Araucaria imbricata in the North of Ireland.—We have been informed that perhaps the finest specimen of the Chili Pine to be found in Ireland is growing at Ballymacool, the beautiful residence of Mr. J. R. Boyd, near Letterkenney, Co. Donegal. It is over 40 ft. high, faultlessly symmetrical, feathered to the ground, and not a brown leaf on it.—'Irish Farmers' Gazette.' [We had supposed the Woodstock tree to be the finest in Ireland; it would, perhaps, be as well if the exact size of this Donegal specimen were given.]

Longfellow's Chestnut Tree.—We read in a Boston paper that another venerable tree has been cut down and carried away. It stood in Brattle Street, Cambridge, U.S., and was the identical "spreading Chestnut-tree" under which the "village smithy" stood. "The smith—a mighty man was he," but the Boston people do not seem to know what became of him. Among other souvenirs, a chair is to be made of the old tree, as a present to Longfellow, who immortalized it.

Shade Trees.—27,700 shade trees are now growing in the streets of Washington, 19,000 of which have been planted within the last three years. Although this is by no means a very large city, a variety of kinds is planted.

The "Major Oak" at Thoresby Park, Nottinghamshire.

THE FRUIT GARDEN.

MELON CULTURE.*

In order to cultivate Melons successfully a structure of some kind must be employed, and as an ordinary garden frame is most generally used for the purpose, I shall devote the principal part of this paper to Melon-growing in frames. The best Melon frame is one with two lights, and its dimensions should be about 9 ft. long, 6 ft. wide, 2 ft. 6 in. in height at the back, and 15 in. in front. The bed on which the frame is to be placed should consist of manure and leaves that have been previously well stirred and sweetened so that no rank steam may arise after the bed is made; its depth should be in proportion to the season at which it is put up—for example, if in March, which I consider sufficiently early, it should be quite 5 ft. high at the back and 3 ft. 6 in. in front; but if in May, with a view to having Melons ripe in August, a much less amount of material would be sufficient, and in either case the bed in the first instance need not be more than 1 ft. wider than the frame all round. When the bed is made up examine it daily for a time by means of a trial-stick, and when its heat has fallen to 100° or 120° the soil may safely be put in. I generally make what is termed a heap or hillock in the centre of each light, and in a day or two, when the soil has become warmed through to the top of the hillock, I set the plants. It has just occurred to me that perhaps I ought to have said something about raising the plants before planting them, but as the majority of cultivators begin growing Cucumbers much earlier than Melons, the Cucumber frame would naturally suggest itself as the proper nursery for Melon plants, instead of putting up a frame specially for that purpose. Many prefer what is termed a good, friable, turfy loam for Melons. I have tried many sorts of loam for them, but I have always found that the stiffer or more retentive the soil, provided it was not absolute clay, the greater perfection the Melons attained, and the fruit was better set and better flavoured than if grown on lighter soils. Plants which have been previously prepared (three in a small 48-sized pot) may now be planted (but not too deeply) on the top of the hillock, taking care that the collar of the plant does not sink below the level of the other soil, an error which gives rise to one of the principal causes of failure in Melon-growing, viz., shanking, an evil created by the water remaining about the collars of the plants. Great attention will now have to be paid to giving air on all favourable occasions, especially in the earlier months of the year, always avoiding cold draughts. I sometimes hang a piece of tiffany along the back of the frame to sift, as it were, the air, and in the early months of the year this little device should not be neglected. Watering, also, must not be carelessly done during early cultivation; but in the summer they will require liberal supplies, and if the soil be not naturally rich, a little liquid manure occasionally administered will greatly benefit them. Fresh soil should be added as often as the roots show themselves round the sides of the hillocks until the frame is full, and at all periods of earthing make the soil tolerably firm, but especially at the final earthing all over the surface. I would mention with regard to adding fresh soil (and this remark should receive attention, especially in the earlier months of the year), that it should be placed in a warm situation some days previous to being used, if possible in a Vinery or Peach-house at work. A moist condition of the soil is necessary to ensure a free growth, light, air, and a proper temperature, making that growth short or long jointed, fruitful or barren, in proportion as they are judiciously or carelessly given when the plants are in bloom; the surface of the soil, or at any rate the atmosphere of the frame, should be drier at the time of setting than at other times.

I consider artificial fertilisation very essential at all seasons for ensuring a crop of Melons. I do not mean that if the female blossoms be not artificially fertilised you will not have a crop of fruit, but that if you fertilise the blooms you will have them swell off more uniformly—a consideration of some importance, for I have in some instances observed that if one or two fruits take the lead, there has been a difficulty in

getting a satisfactory number to swell off. It is a good practice to give a good watering a few days before the flowers begin to open, to have the bottom-heat brisk, and to admit as much fresh air as the state of the weather will permit. About mid-day examine the plants, by which time the pollen will be dry, and fertilise any blooms fit for the operation. When the fruit has set and begun to swell, water will be needed once or twice a week, if the linings of the bed be in good condition and the heat brisk; but in this, circumstances alter cases, and no cut-and-dried rules can be laid down; however, one thing should be borne in mind, that if possible the centre stem of the plant, whence the branches radiate, should be moistened, or evil results will soon set in. As to stopping and training, it is presumed that the plants were stopped previous to planting out; and, supposing them to be stopped at the second rough leaf, they will each push three or four shoots, and these do not travel far before they push laterals, which, if left, only crowd the centre of the plant to no benefit, for these early laterals seldom produce female blooms, and if they did it would not be desirable to retain them, as the plants would not yet be sufficiently established to swell off fruit to perfection. After selecting, say six or eight of the strongest shoots, I train them by pegging them down, one exactly towards each corner of the frame, one front and back, and one to each side; this will be found ample. I do not stop any more until the respective shoots have reached within a foot of the corners, fronts, back, or sides of the frame, and I have taken off all the laterals up to about five or six, which I leave at the point of each shoot after stopping; it will be found that the laterals now produced are very much stronger than any that have previously showed. These will be sure to produce fruit blossoms, and due attention to setting and after-management will bring the crop to perfection. The number of fruit to be left on each plant must be determined by the sort. Some, like Scarlet Gem, will permit of ten or a dozen to a light; while of the larger kinds four or six would be considered a good crop. When the fruit approaches maturity, the greater part of the spray-like laterals should be thinned out, at no time should they be allowed to crowd the frame or shade the fruit. It is a good plan to elevate the fruit a little above the foliage, as it keeps drier, and exposes it to the full action of the sun, no fruit being improved more in flavour by sunshine than the Melon.

I will very briefly now allude to Melons in houses. The sort of house, advocated by Mr. Bridger at our last meeting as being suited to the cultivation of Cucumbers, is just what would suit Melons, especially his water-tank for supplying the bottom-heat. I am a strong advocate for tanks as furnishers of bottom-heat for Pines, Cucumbers, and Melons, and, in fact, for every plant that requires bottom-heat, or for propagating purposes. The soil and general treatment would be the same as for Melons in frames. I train a limited number of shoots up the roof-trellis, and do not stop them finally until they have made considerable growth. Melons require more liberal syringing in a house than in a frame, to keep down the red spider; and should they need fumigating at any time, either in houses or frames, by all means use Tobacco for the purpose, in preference to Tobacco-paper, rag, or any other material, for I have seen many crops of Melons destroyed or made unsightly by fumigating with Tobacco-paper, while I do not remember a single instance of their being injured by Tobacco, however strong. It is hardly necessary to enumerate the varieties, as nearly every gardener has his own pet sort; but among the best for frames are Beechwood (if obtained true) and the old Bromham Hall, Golden Queen, Golden Perfection, Egyptian, Green-flesh, Read's Scarlet-flesh, and Scarlet Gem are also all excellent kinds. For a house—Trentham Hybrid is first-rate, as are also Hybrid Cashmere, Striped Housanee, Persian Hybrid, and Dampsha.

As regards late Melons, little has been done; nevertheless, a moderately well-flavoured Melon at Christmas would be a desirable acquisition. I feel that late Melons can only be secured in one way, and that is, to have a variety that will keep a considerable time after being cut from the plant. Some years ago, the late Mr. Edlington said that some argue that a Melon is comparatively flavourless, except in summer or early autumn; in contradiction of such an opinion I can affirm that the fruits furnished by me

* Read by Mr. Easton, at one of the Wimbledon Gardeners' Improvement Society's Meetings.

in November and December are of good flavour; now I should like to know what were the sorts he was cultivating at that time, as the subject is worth attention. I recollect some few years back that Mr. Beech, gardener to the Marquis of Northampton, had a variety of Dampsha, which he told me he could keep for two months after it was cut. I thought I would mention this (to me) rather interesting fact, as I think that the man who can introduce a really good, keeping Melon would be entitled to as much credit as those who introduced Lady Downes and other late-keeping Grapes.

FOOD FOR TREES IN ORCHARDS.

The proper management of fruit trees depends greatly on the supply of food to the roots; and to understand the best mode of applying this food, it is necessary to know the extent, depth, and character of the roots; otherwise it is like attempting to feed an animal in the dark; the food may be all placed where it is inaccessible. Having given special attention to this subject for more than twenty years, and frequently presented its importance to the public, the writer naturally feels much interest in having it well understood by fruit culturists generally. The extent to which trees throw out their roots in all directions is becoming better understood. It was formerly scarcely appreciated. The rule, that the roots will be found as far from the base of the trunk as the entire height of the tree, after many examinations has invariably been found within bounds. In many cases they extend to a much greater distance. Even young dwarf Pears, the Quince roots of which are commonly supposed to be quite short and confined in a dense mass of fibres near the base of the tree, I have easily traced to a distance from the tree equal to its height. Prof. Beal, of the Michigan Agricultural College, showed me last year an orchard on the college grounds, which had been fourteen years planted, the trees being from 12 to 14 ft. high. The roots were found an examination to be thickly matted beneath the whole surface, or had extended so as to meet and cross each other, and were traced within 6 ft. of the next rows, which were 33 ft. apart. In other words, these trees, not over 14 ft. high, had thrown out roots to a distance of 27 ft. The soil was a medium loam, and there is no reason to believe that this extent of roots was an exceptional case. There is no question that the roots of Apple trees generally extend to a distance greater than the height. A part of the orchard just referred to, had been ploughed over the whole surface, after it had remained many years in Grass. The result was a great increase in the vigour of the trees. Another portion was ploughed with the exception of Grass circles 10 ft. in diameter, left at the base of the trunks. There was no apparent difference in the vigour of the trees where the whole surface was ploughed, and where the 10 ft. circles were left in Grass. This result is easily explained. The roots extending 27 ft. on each side formed a circle of fibres for each tree 54 ft. in diameter, and this circle had an area more than twenty-four times as great as that of the 10 ft. circle of Grass. The reason is therefore obvious why no apparent difference was observed in the thriftiness of the trees where all the surface was cultivated, and when the circles of Grass remained around them. Another portion of this orchard was left entirely in Grass; and still another had 10-ft. circles cultivated around the base of the trunks. There was no perceptible difference in the appearance of the trees, the foliage in both cases being alike yellowish and unthrifty in appearance, and the shoots of feeble growth. The cultivated circles, 10 ft. in diameter, constituted but a twenty-fifth part of the area covered by the whole roots, as already explained.

From these experiments it is obvious that but little advantage can result from the common practice of forming circles about fruit trees which stand in Grass—unless the circles are very large, and for the first year or two after transplanting, while the roots are comparatively short. I tried an experiment to determine the distance at which Peach trees receive nourishment through their roots. A row of trees was set a few feet distant from each other, and when they were 9 or 10 ft. high, the whole ground was permitted to become covered with a dense growth of Grass. The annual shoots were not over 8 in. in length. At one end of the row the surface was covered with a quantity of manure. The tree standing nearest to it (about 2 ft. distant) sent out shoots 4 ft. long. The second tree, 7 ft. off, had shoots 2½ ft. long. On the third tree, 15 ft. distant, the shoots, were 14 in. long; and on the fourth, 23 ft. off, and too far for the roots to reach the manure, the shoots were only 8 in. long. The striking fact was here presented, that the tree 15 ft. from the manure, although but 10 ft. high, received nourishment enough through a few roots on one side to double the growth. The circle of roots, therefore, belonging to this 10-ft. tree, must have been at least 30 ft. in diameter. These, as well as many other experiments

which might be cited, prove the error of the common practice of applying manure to the roots in a circumscribed circle. Broadcast culture and broadcast manuring should be given to the whole surface of the orchard, unless to save labour small portions of Grass be left at the foot of the trunk in horse cultivation.

There are other questions in the management of orchards which must be answered variously, according to the circumstances of the case. One of the questions refers to the depth to which cultivation should be given. Where the sub-soil is hard and poor, and nearly all the fertility of the land lies within a few inches of the top, the treatment must be very different from that employed on a deep, rich soil. On such a shallow soil, the trees are much more susceptible of the influence of surface culture or top-dressing with manure. The roots extending very near the surface, it becomes more important to cultivate shallow. It often happens that a top-dressing of manure on such land is the very best thing for the trees; and to allow a dense growth of Grass without manure, may be the worst treatment for their growth and success. I have just examined the roots of large trees in an Apple orchard standing on land with a comparatively loose and fertile sub-soil. The majority of the roots were 2 ft. below the surface; some of them nearly an inch in diameter were found 4 ft. below, and they appeared to run much deeper, probably 7 or 8 ft. In this orchard, after the trees were twenty years old, the ploughing of one part and the Grass in another made but little difference in the growth. The roots were far below the reach of the plough, and the roots of the Grass on the surface drew but little nourishment from 2 ft. below. Cultivating the surface, and top-dressing with manure, had comparatively little effect on the trees when old, although making a great and obvious difference while they were young and the roots nearer the surface. There are many soils, however, where most of the roots are not a foot below the surface, particularly while the trees are young. For these, two modes of treatment are adopted by cultivators. One is to keep the top mellow and clear of Grass and weeds by ploughing and harrowing. The other is to allow the ground to become covered with Grass. Much discussion has arisen on the comparative merits of the two modes. An examination of the condition of the growing tree will point out the course to pursue. If, as often happens on the rich soils of the south and west, the trees have too much rankness and succulence, rendering them liable to injury from changes of the weather, it would obviously be important to seed the land to Grass, and thus check the growth. If the trees be feeble, indicated by short and stunted annual shoots, additional vigour must be imparted by cultivation or manuring, or both. The character of the soil and climate will vary the management in different localities and regions, and no rule can be laid down for constant and invariable adoption. Yet, throughout the Northern and Eastern States, and in many portions of the Middle States, very few orchards will possess sufficient vigour unless cultivation or top-dressing be given to the soil. As a general rule for guidance in determining what treatment to adopt, the annual shoots may be examined; and if in young orchards they are less than 2 ft. in length, or in bearing orchards much less than 1 ft. in length, they should receive additional stimulus by means of manure or cultivation.

The question often occurs and is frequently discussed—Which is the best—to manure a Grass surface, or to give clean cultivation without manure? On very shallow soils, manure may be the most effective. But even then, a shallow and thorough cultivation may answer all the desired purpose. The addition of a moderate top-dressing to such a cultivated soil, will accomplish more than heavy manuring on Grass. The question will resolve itself into one of economy. Ploughing once and harrowing five times subsequently will not usually cost more than £1 per acre altogether. An equal effect produced by manure would require at least fifteen two-horse loads. At 4s. per load, and half as much more for drawing and spreading, these would amount to more than four times as much as keeping the ground clean by cultivation. In many instances the cost of manuring would be much greater; in a few possibly less. In some cases where cultivation is difficult, manuring may be used with advantage; and where valuable crops of a hundred pounds' worth of fruit per acre are obtained, as for example with the best Pears, the annual cost of £4 or £5 for manure would be a small portion of the net profit. On soils of moderate fertility, the practice of allowing Grass to grow with young or newly-set fruit trees, is one of the most common causes of failure. All plants when crowded are checked in vigour. Weeds and Grass lessen all garden crops. Indian Corn thickly sown will not bear ears. For the same reason where trees and Grass occupy the same ground, the evils of a crowded growth occur, and the trees cannot flourish so well as where they have the sole occupancy. The exception (partially) is where the roots of the trees, as they become old, run far below the Grass in the deep, rich, and porous sub-soil. I have usually found the shoots of young

Peach trees which stood in mellow, clean soil, or with well cultivated hood crops, as Corn, Potatoes, or Beans, to grow 2½ ft. to 3 ft. in a single year. When allowed to stand in Grass, I have never seen the shoots a foot long while the trees were young, unless within reach of manure or cultivated ground through their long roots.

Quackery has been defined as the application of the same remedy to all diseases. It should never be adopted in the cultivation of fruit, but the treatment should vary with the condition of the soil and locality. The planter who succeeds well with his trees in Grass, in land of great fertility, or with high manuring, should not prescribe Grass for orchards in all other soils and places. The man who has a shallow soil, and who has injured his orchard by severely mutilating the roots with the plough, because they are all near the surface, should not object to the thorough ploughing of deep soils. I have seen an orchard which was ploughed early in the spring, after lying long in Grass, and the roots so severely cut that at least one cartload per acre was picked up and drawn off after the operation. Yet, as this was done in spring before growing had begun, and as there were plenty of roots remaining deeper in the soil, a positive benefit was derived from the ploughing, the cultivation overbalancing any injury by the mutilation of the roots, and greatly increasing the quantity as well as improving the quality of the crop. But if this deep and thorough ploughing had been performed after the trees were in leaf, or if the soil had been so shallow as to throw most of the roots within 6 in. of the surface, the result would doubtless have been disastrous.—JOHN J. THOMAS, in "Proceedings of American Pomological Society."

Gumming in Peach Trees.—I should be glad if any of your subscribers who happen to live within a mile or two of the sea-coast, would state their experience with regard to outdoor Peaches. This place is about two miles from the coast, and I find that outdoor Peaches gum badly, a circumstance that cannot, I think, be attributable to an unsuitable compost, as we are generally taught to suppose, for they are grown in a loamy soil, inclined to be a little strong, and resting on a dry, shady sub-soil; wherever, too, there is a spring in the neighbourhood the water is found to be quite soft and free from lime; in fact, the soil is just what my experience has taught me to desire for the Peach. At a neighbouring place the Peach trees are suffering from the same disease, at least the symptoms are alike; but Peaches that are protected by glass are perfectly healthy, and they are in the same kind of soil as those out-of-doors. My impression is that bad gumming in my case is due to atmospheric influence.—A SUBSCRIBER, *Memblad, Ivybridge, South Devon.*

Grapes Over-thinned.—Over-thinning bunches of Grapes is said (see p. 484) to spoil their appearance when placed upon the table—they fall, it is stated, all over the place, instead of lying compact and firmly as they ought to do. I have heard this objection to over-thinning made times without number, but I would ask—Is it a valid one? Is it true that a bunch of Grapes, firm and rigid (I have seen bunches that could be held straight out by the hand when taken by the foot-stalk), looks best on the table, or that it dishes up most artistically? I do not put this question to cultivators only, but also to the artist readers of THE GARDEN. Culturally speaking, the firm bunch is the most creditable, for in most varieties a sturdy bunch is generally associated with high health and vigour; but on the dessert plate, it has, in my opinion, a very ungainly appearance. I defy anyone to make anything else than a "heap" of three or four stiffly packed bunches on the table; whereas, a limp bunch, that will "fall all over the place," is accommodating, and is just the kind of bunch which an artist, in the true sense of the word, would prefer to deal with. A painter would have nothing to do with stiff, dumpty bunches; and I apprehend the rule by which he is guided holds good in setting up fruit for dessert. I confess that I have, indeed more than once, cut off limbs and shoulders and otherwise "abused" a good bunch to make it fit well into a basket of fruit.—C.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Vroegse Van den Laenen.—The above is the name of a Grape which is extensively grown against gable ends in Belgium, and which is said to ripen early in the autumn even there. I fancy it would prove a valuable kind for the United Kingdom, and shall be glad to hear if any of your readers know of it or have tried it.—V.

A Disagreeable "Protector."—A French Vine-grower, near Bordeaux, to protect his crops from the frost, recently placed four large heaps of wood and dried leaves, saturated with oil, in a four-acre lot, and set fire to them. They produced a thick, black smoke, which hung over the ground like a mist, and the temperature became two or three degrees higher than in adjoining fields. The cost was estimated at 4s. an hour for each acre.

THE FLOWER GARDEN.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

The first time of blossoming of a plant is not always the most attractive one, and, therefore, we desire again to refer to plants mentioned as in flower one or more weeks ago to speak of their fuller beauty now. The Snowdrop Anemone, for example (*A. sylvestris*), which has long shown its buds, was, during the past week, in full beauty; grown in some quantity in a wood, or copse, or shrubbery, it is one of the loveliest plants we have, and being quite hardy and free, it is easily naturalised. The blue prostrate *Lithospermum* puts forth feeble flowers now and then throughout the winter and spring, but now it is a carpet of little cups that rival the *Gentians* in brilliancy, a few tufts of the smaller *Hooped Petticoat Narcissus* intermixed with this would produce a rich effect. A plant of the snowy-flowered *Arenaria montana* straying through a tuft of *Lithospermum* forms a pretty mixture. A handsome *Lupine* well worth growing is *Lupinus Nootkatensis*, a very hardy kind, which has already formed seed-pods, though it, like all hardy plants, has suffered from the prolonged cold winds more than they have for many years at this season. This *Lupine*, though uncommon in London gardens, is, according to Mr. A. Perry, quite common in the Burnley Valley in Lancashire. It sometimes happens that plants rare or quite lost about London are found plentifully in some country district where they have escaped the great destruction caused in the great incursions of the scarlet horde. The loveliest effects of the season are afforded by the various Pansies and large hybrid Violets now in flower. The continued dry cold seems to have injured them but little, and their purity and effectiveness of colouring are marvellous. It is interesting to notice the new and distinct forms that are added to these from time to time, as, for example, the white-edged kinds and the deep rich bronzy-hued ones. The effect of good plants of *Trillium grandiflorum* in shady places—the large pure white flowers on the ample rich green foliage—is very beautiful. The *Globe-flowers* (*Trollius*) have also been magnificent throughout the week; we have nothing more precious. Like the *Daffodils*, they seem not to be affected by the hard weather, and the rich globes of clear yellow of the English *Globe-flower* and its varieties, and the bright orange of *T. napellifolius*, are surpassed in beauty by no hardy flowers of our now rich garden flora; they will grow anywhere, and are seen to perfection in fully exposed places. They will prove splendid subjects for naturalisation in copses, shrubberies, woods, and, in fact, in almost any position where really effective flowers that require no care are desired. The following is our list of plants noted as in bloom early in the week:—*Cypripedium montanum*, *C. pubescens*, *Anemone narcissifolia*, *Cyclobothra pulchella*, *Ranunculus uniflorus*, *Androsace carnea*, *Ranunculus Gouani*, *Saxifraga aquatica*, *S. lancostana* and many others, *Sedum ternatum*, *Erodium Manescavi*, *Geranium sanguineum*, *Anemone palmata*, *Alyssum atlanticum*, *Silene maritima* in variety, *Mertensia paniculata*, *Potentilla albaica* (the most vigorous and stately of *Tulips*, a yellow kind: Ware's Nursery, Tottenham), *T. Celsiana*, *Scilla algeriensis*, *Lychnis viscaria*, *Asphodelus ramosus*, *Campanula speciosa*, *Lupinus Nootkatensis*, *Aquilegia Wittmanniana*, *A. formosa*, *Gentiana verna*, *Lychnis dioica* fl.-pl., *Cerastium* in var., *Saxifraga Cymbalaria*, *Euphorbia Chamæcyparissias*, *Pæonia tenuifolia* var. *Smoutii*, *Hyacinthus amethystinus* albus, *Symphytum bohemicum*, *Saxifraga Cotyledon*, *Trientalis europæa*, *Armeria Cephalotes*, *Thlaspi latifolia*, *Erodium macrodonium*, *Potentilla alpestris*, *Lupinus polyphyllus*, *Thermopsis fabacea*, *Centaurea uniflora*, *Sempervivum anomalum*, *Valeriana pyrenaica*, *Smilacina stellata*, *Iris sibirica*, *I. iberica*, *Comfrey*, *Geranium maculatum*, *Pæonia Russi*, *Potentilla dubia*, *Heracleum Leichlini*, *Onosma tauricum*, *Hutchinsia alpina*, *Dryas octopetala*, *Sempervivum Boutigianum* and a few others, *Rheum officinale*, *Arrum orientale*, *Cimicifuga borealis*, *Craspedia Richei*, *Pentstemon nitidus*, *Scorzonera inæqua* scapo, *Lasthenia glabrata*, *Erigeron bellidiflorus*, *Aster salsuginosus*, *Centaurea Cyanus*, *Allium neapolitanum*, *A. triquetrum*, *Platystemon californicum*, *Alyssum spinosum*, *Pæonia officinale* in var., *P. anomala*, *P. decora*, *P.*

Paeonia edulis flore-pleno.

Paeonia Wittmanniana.

Bean-like *Thermopsis* (*T. fabacea*).

Double White *Lychnis* (*Lychnis dioica* fl.-pl.)

Double dwarf *Lychnis*
(*Lychnis viscaria*, var. *flore-pleno*).

(*Paeonia officinalis* fl.-pl.)

Great Alpine *Saxifrage* (*Saxifraga Cotyledon*).

Great *Asphodel* (*Asphodelus ramosus*).

Sea *Catchfly* (*Silene maritima*).

Mountain *Arvens* (*Dryas octopetala*).

Blood-red *Geranium* (*G. sanguineum*).

Common *Lupine* (*Lupinus polyphyllus*).

mollis, *P. daurica* and various others, *Papaver orientale*, *Arum crinitum*, *Viola cornuta*, *Antennaria candida*, *Cyclobotria lutea*, *Iberis gibraltarica*, *Erinus alpinus*, *Tellima grandiflora*, *Geranium Robertianum album*, *Sarracenia purpurea*, *Lixias* in variety, and various kinds of *Sparaxis*.

HANDSOME IRISES.

AMONG hardy perennial plants there are certain kinds which, on account of their showy character in general, or of their striking forms and habits, rank among the aristocracy of flowers, rendering them well worthy of very special and general culture. Among such are, for instance, the Phlox, the Peony, the Larkspur, and most decidedly the many most strikingly-interesting varieties of Iris, which, to be more appreciated, only require to be more generally known. Their sword-like leaves, and large beautifully-formed flowers, produced in great profusion, embracing such a variety of colour and rich pencillings, give them very much the same position among hardy perennials that Orchids occupy among indoor tender plants. Besides, they are of the easiest culture, thriving in almost any soil, and equally at home in comparatively swampy grounds by the lake or pond side, and in the ordinary mixed border. Small portions of their fleshy prostrate rhizomes, if once planted and left to take care of themselves in a great measure, soon increase into large stools, yielding hundreds of interesting blossoms. They are, moreover, so perfectly hardy, that the severest weather of this country does not injure them. Naturally, they do best in a rather heavy moist soil, but they also succeed in any soil well worked and manured when planted.

There is now an almost endless variety of Irises, and for the information of these persons who may desire to form a select collection of them, the following list may be found useful:—*amabilis*, pale blue, lower petals velvety-purple, reticulated with white—very abundant bloomer; *Antiope*, metallic blue, lower petals violet, pencilled with pale straw; *Arlequin Malarias*, white, feathered and edged with violet, lower petals purple, reticulated with white; *Arnols*, violet, suffused with bronze, lower petals rich velvety-purple, reticulated with orange and white; *Augustus*, azure-blue, lower petals 'pure violet, reticulated with white; *anrea*, chrome yellow, lower petals paler yellow, reticulated with sulphur; *Bocage*, pale lavender, lower petals purple, feathered with white; *Bridesmaid*, white, suffused with lavender, lower petals pencilled with reddish lilac; *Chameleon*, indigo blue, flaked with purple, lower petals pale violet, reticulated with white; *Comte de St. Clair*, pure white, tipped with violet, lower petals beautiful purple, reticulated with white; *Cordelia*, rosy lilac, lower petals rich rosy purple, margined with white; *Cytheree*, lavender blue, lower petals light purple, veined with white; *Darius*, chrome yellow, lower petals purplish-lilac, reticulated with white; *Dr. Berenice*, coppery-brown, lower petals ruby-purple, reticulated with orange and white; *Exquisite*, bronzy-sulphur, lower petals rich purple, veined and margined with sulphur, bearded with golden yellow; *Fairy Queen*, white, feathered and grained with purple; *Gideon*, yellow, lower petals crimson-purple, heavily veined, and reticulated with sulphur and white; *Hericart de Thury*, chrome yellow, lower petals brownish-crimson, veined and reticulated with sulphur and white; *Imogene*, bright lavender, lower petals soft azure blue, centre white; *Jacquesina*, reddish-bronze, lower petals crimson, reticulated with yellow and white; *La Fristosse*, primrose, lower petals crimson, heavily reticulated with yellow and white; *Leopoldine*, yellow, lower petals purple, margined with sulphur yellow, heavily striped with white; *Madame Chereau*, white, all the petals beautifully edged and barred with violet; *Paquita*, purple, with light centre, lower petals reticulated with white; *Poitcan*, white, suffused with lavender, lower petals rich purple, reticulated with white; *Racine*, primrose, suffused with lilac, lower petals rosy-purple, reticulated with orange and white; *spectabilis*, velvety-purple, shaded with black; *Unique*, white, lower petals purple, heavily veined and margined with white; *Victorie*, satiny-white, blotched with purple, lower petals violet, purple-veined, and reticulated with white; *Walner*, azure-blue, lower petals light purple, veined with white. The thirty kinds named above are really splendid varieties; and, being hardy plants that can be purchased for about 18s. per dozen, any one who adds them to his mixed borders of hardy plants cannot fail to derive much pleasure and interest from them.

D. THOMSON, in "The Gardener."

Diseased Phloxes.—Is there anything known of a disease that affects Phloxes, more particularly *P. decussata*? Mine have suffered severely this season, and they did so partially last year. After they commence growing, they appear to experience a sudden

check—sometimes all the shoots, sometimes one or more. The stalk thickens, the leaves shrivel, and they look as if the sap had been checked and coagulated, so to speak, in the stems. They never recover during the whole year, and do not flower. Phloxes appear to me to be more delicate than they were formerly. Is that really so? Any information on the subject from your correspondents would oblige—Rose.

HOW TO PACK FLOWERS.

THESE are few persons who have been accustomed to receive cut flowers by post who have not experienced the mortification, on opening the box, of finding them all fallen to pieces, crushed, or otherwise injured. We therefore propose to give a few directions on the subject, and believe that, if attended to, both the sender and receiver will be spared the mortification alluded to. Always cut the flowers early, in the cool of the morning, and when in their prime. Take a piece of cotton-wool, wet it, and wring it out, then twist it about the stalk. If tin boxes be used, they must not have sharp corners, or they will be rejected at the post office, but, when properly made, they excel all others for the purpose in question. At the bottom of one of these place a piece of stout brown paper (if thin, double it); let this be well damped, then lay the flowers carefully in, placing a piece of silver or tissue paper between each, to prevent their bruising each other. Over all place a piece of the same paper, and on this a little cotton-wool. Cover the box with paper, and the flowers will reach the extremities of the kingdom in good condition. Let us add the modes of faulty packing, to warn our friends against their adoption:—1. Placing the flowers in contact with dry cotton-wool, which clings to them, and abstracts their moisture. 2. Putting them in tin boxes, such as have contained lucifers, &c., which invariably get crushed in passing through the post office. 3. Putting the cotton-wool about them too wet, the moisture from which gets shaken over the flowers, and spoils their colours. 4. Cutting the flowers after exposure to the sun, which ensures their falling to pieces on the journey; this also occurs if the blooms be stale. Some persons, sending seedling flowers for an opinion regarding their merits, think it best to cut them when not fully open, knowing that they will expand in water; but they should learn that they do not show their true character, either in shape or colour, under such circumstances. A better plan is to cut off the pistil directly it can be done; this will ensure the flower lasting a considerable time.—"Florist."

FLOWERS FOR THE POOR.

PERSONS who love flowers must be possessed of some refinement. The delicacy and grace of plants, the manner in which they reward by their increased beauty any care bestowed on them, their loveliness of colour, their elegance of shape, and their sweetness of perfume, are all points which tend to make a love of plants a great instrument in the cultivation of some of the best parts of our nature. Very much has been done of late years to encourage the love of flowers among the population of our great cities. It seems to us that of late years of flowers, and of such hardy-growing plants as will stand the smoke of towns; while, among the poor, flower shows and distributions of plants from the park gardens have done much to encourage flower growing and to bring plants within their reach. The late Lady Augusta Stanley, among her many good works, was specially interested in the cultivation of the love of flowers among the poor, and at no time was she more happy than on the day when the Annual Westminster Flower Show was held close to the Deanery, and the poor people came to the *fiets* as well as the rich. Another good work, in which many ladies have been interested, and in which even children have been able to take their part through the sweet agency of flowers, has been the collection in the country of some of the treasures both of garden and hedgerow, and the sending them into towns where, through the help of other ladies, they have been distributed to the chambers of the sick and aged poor. All of us know how wearisome the walls and furniture of even the best-appointed sick room becomes when the tired eyes gaze day by day on the same objects in the same places. A new book, a change of a picture, a new ornamental trifle, gives a new look to the too familiar objects. But nothing gives so thorough a change or refreshment as a plant or a flower. The flower need be of no uncommon kind. The poorest little wayside blossom is interesting to the eyes that have been long debarr'd from seeing the country. Fresh flowers are a gift which all may offer and all may accept; and nothing sent to an invalid affords a more acceptable present. In our columns we have more than once advocated the cause of "Flower Missions," as they

have been called; and, as spring advances and the near approach of summer is hoped for, we would venture to recall the subject to the attention of our readers. Not flowers alone, but Mosses, fine Grasses, sprays of Hawthorn, and other tree blossoms; even beautiful branches of leaves are much prized and welcomed in the homes of the sick and aged poor. Let those who have worked for flower missions before either continue or begin with renewed energy their pleasant ministrations; and let others who have not done so before take up this work, assured that they will thereby be dispensing great and pure pleasure.—“Queen.”

MOSS ROSES.

The original, or old Moss Rose, is supposed to have been introduced from Holland in 1536, but as to its origin no satisfactory account has ever been given. It is, however, generally believed to be a sport from the Old Provence, and from the close resemblance which the flowers bear to those of that kind except as regards the mossing—this is doubtless correct. Although several hundred varieties of the Moss Rose have been raised since the introduction of the original, none are superior, if equal to it, in point of beauty or fragrance; its long handsome buds, covered with tufts of the most beautiful mossy excrescence, make it interesting and beautiful in all its stages. The Crested Moss Rose, or, as it is sometimes

Common Moss Rose.

called, Crested Provence, is most peculiar and beautiful; the beauty of its bud alone should claim for it a place in every garden. The Moss Roses are mostly of delicate growth, though some are vigorous and robust in habit, and form good standards, but, as a rule, they all succeed best when grown upon low stocks, or otherwise upon their own roots; the latter mode is best suited to the old Moss, and no garden wherever Roses are grown should be without a bed or two of this old favourite. It requires rather high cultivation and close pruning, and, generally speaking, rather better treatment than ordinary kinds. In wet or cold damp soils it does not thrive, a warm dry soil being required for it, and this well supplied annually with manure. If at any time plants of it appear to decline in health, they should be taken up and replanted in fresh loamy soil and cut hard back. The following descriptive list, taken from my Rose book recently published, contains all the best of the Moss Roses at present in cultivation:—

Alice Leroy.—Rosy pink, with handsome mossy buds, moderate size, and full, free-flowering, and good habit; a good and useful Rose, forming a good standard.

Baronne de Wassenaer.—Deep rose, very large and double, buds moderately well mossed, habit vigorous; a very showy and useful Rose, and one which forms a good standard.

Celina.—Velvety-purple and crimson, buds well mossed, and very cautious; flowers moderate size, full, and when newly opened very

beautiful; habit of growth rather too dwarf; requires rich soil and close pruning.

Clemence Beaugrand.—Soft pink, a handsome and well-mossed bud, flower large, having a fine broad petal, not very full; a good Rose, of free habit.

Common, or Old Moss.—Pale rose, globular, very large and full, and deliciously fragrant; buds well mossed, habit free; the most beautiful of all Moss Roses, and one which should be grown upon its own roots in rich soil.

Comtesse de Murinais.—Pale flesh when newly opened, changing to pure white, large and double, though not very full; habit robust; one of the hardiest of the white Moss Roses.

Cristata, or Crested Provence.—Pale rosy-pink, changing to pale rose; globular, very large, and full; buds beautifully crested; an interesting and beautiful Rose.

Frederic Soulie.—Crimson shaded with purple, large and full; a well-formed and excellent Rose, and one which, like the last, has a moderately vigorous habit.

Gloire des Mousseuses.—Pale rose, the outer petals whitish, one of the largest and best of Moss Roses; buds large and handsome; habit very vigorous, forming a good standard.

Gracilis, or Prolific.—Deep pink, buds handsomely mossed, flowers large, globular, full, and of good shape; an excellent Rose, moderately vigorous in habit.

John Cranston.—Shaded violet-crimson, colour rich and good, flowers of moderate size, expanded, full, and well formed; habit free.

Julie de Mersant.—Rosy-pink, moderate size, blooming in clusters, buds small and very pretty.

Lanei.—Deep brilliant rose, bud round and handsome, and well mossed; flowers very large, full and excellent; one of the best of the Moss Roses.

Luxembourg.—Purple-crimson, flowers large and full; a very old variety, of most vigorous habit; useful as a pillar Rose, or as a tall standard.

Marie de Blois.—Bright rose, large and full; an excellent variety, with well mossed handsome buds; habit robust and good.

Princess Royal.—Pale flesh, very compact and full; flowers rather small, though quite distinct, and very beautiful; habit moderate.

Reine Blanche.—Pure white; flowers of good size and tolerably double.

Unique.—Pure white, in dry weather slightly tinted; evidently a sport from the Old Unique Provence, which the flower much resembles, with the addition of having mossy buds; habit dwarf and delicate.

White Bath.—Paper white, very beautiful and distinct; one of the best white Moss Roses in cultivation. JOHN CRANSTON.
King's Acre, Hereford.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Perennial Mountain Forget-me-not (*Myosotis rupicola*).—This promises to be extraordinarily beautiful this season. Hundreds of tufts, scarcely more than 1 in. high, are covered with sheets of flower-buds, some already expanded and most lovely. Even in small pots they are showing masses of flower.—JAS. BACKHOUSE, *Tork.*

Cyclamen-leaved Windflower (*Anemone palmata*).—Mr. Harpur Crews says (see p. 466) that this barely exists, and does not flower, with him. Here it thrives and flowers freely in the open border in ordinary garden soil. When in bloom it is a showy and beautiful plant, its only fault being that it only unfolds its fine bright-yellow flowers during sunshine, being seemingly reluctant to exhibit its beauties during the afternoon or on a cloudy day.—Oxor.

Adonis vernalis.—It is strange that this fine old and perfectly hardy plant, with its brilliant tufts of Anemone-like flowers and beautiful foliage, is not more generally cultivated than it is. I have a fine plant of it which has been undisturbed for some six or eight years, and which has produced some three dozen blooms that on a bright sunny day are quite dazzling.—J. W.

Cow Parsnip (*Heracleum giganteum*).—This, one of the earliest of fine-foliaged plants, makes a grand display at this season of the year on semi-wild banks, or as a background plant in large borders; care should, however, be taken to see that it does not over-run choice plants of a weaker kind, as, when once established, it spreads rapidly. Its chief fault is going off early in the season and leaving unsightly gaps, which have to be filled up with other plants.—J. G.

Erythra Crista-galli in the Open Ground.—It is said of this plant (see p. 472) that “it is easily managed by keeping its thick, clumsy root in a dry cellar in winter,” &c. I would suggest, as a far better plan, to leave it in the open ground. The plant is perfectly hardy; it dies down early and comes up late—but, when well established, it sends up stems 5 ft. or 6 ft. long, covered with its brilliant flowers. When grown thus the flowers are of a much richer colour than when grown in a conservatory. I should like to know if it ever ripens seed in England.—H. N. ENZICKER, *Bitton Terrace.*

PLATE XXII.

COX'S ORANGE PIPPIN.

Drawn by H. MYDE.

This is probably the finest Apple in cultivation; and other sorts have had their day, but have settled down into a rank below this. A few years ago there was quite a furore in the pomological world, respecting the wearing out or otherwise of the Golden Pippin and the Ribston Pippin, and the theories of such an able physiologist and raiser of Apples as the late Mr. Andrew Knight, with regard to that matter, have been entirely disproved, for the present healthy character of these two kinds incontestably shows that weakness has not destroyed the Golden Pippin, nor canker eaten up the Ribston Pippin; in fact, there seems no valid reason why varieties of Apples should not last for ever, provided the system of culture be correct, and they be not neglected for novelties: for trees and plants renew their lives with the individual, and are in no way influenced by the life or death of their original or remote progenitors, provided these have not transmitted to them some inevitable legacy of hereditary disease. It even seems possible, by skilful cultivation, to make varieties of vigorous plants outlive such maladies. Granting, for instance, that weakness is hereditary to the Golden Pippin, and canker to the Ribston Pippin, which many have assumed, it is, nevertheless, indisputable that there never were so many clean and healthy trees found of either sort in gardens as there is at present. Cox's Orange Pippin has the advantages of youth and of moderate strength on its side; though not one of the strongest growers, it shows no symptoms of canker, if planted on a suitable site, and cultivated with ordinary care. It comes from a good stock, and if size, colour, form, juiciness, crispness, sweetness, and long keeping be necessary qualifications for a fine dessert Apple, then Cox's Orange Pippin should claim the first position. Its size is that best adapted for effectiveness, viz., medium—neither too large, nor too small. The form is regular in outline, roundish-ovate; the stalk short; eye, medium-sized and open. The colour varies much, according to the site on which it is grown, as is the case with all Apples. Much as colour is valued by many, and often as it is accepted as a test of quality by some, it is at once the most fugacious, capricious, and uncertain characteristic of fruits. Cox's Orange Pippin has, however, all the richest and most pleasing colour of our finest Apples. The ground colour may be defined as green running into yellow, suffused with red streaks, with dark and ruddy red where exposed to the sun. It is a fruit of which the lover of good Apples never tires, and it does not pall on the palate like mealy or softer kinds. It has also a very long season, for it is frequently fit for table in the month of October, lasts good throughout the winter, and may, if carefully stored, be had in good condition even through April. These long-keeping qualities add much to its value, and, to develop them to the utmost, this first-class dessert fruit should be grown in different aspects and of different forms and sizes. It forms a good orchard tree on the Crab or Nonsuch stocks; the longest-keeping fruits are often gathered from such large and free-growing orchard trees. Worked on the Paradise or Doucain stock Cox's Orange Pippin is one of the very best varieties of Apples to form pyramids, bushes, or cordons; on the latter especially the full beauty, quality of the fruit, and fertility of the trees are strikingly brought out. Those grown close to the ground as cordons are almost fit for table as soon as gathered, and are distinguished by a size and quality which even this fine Apple does not always acquire on larger trees. Not only should Cox's Orange Pippin be ranked as equal to the Ribston Pippin as a dessert fruit, but it is also one of the very best for culinary purposes. Those who have never eaten the finer dessert fruits cooked have a new sensation of gastronomic pleasure in reserve, of which they can form no idea from the eating of the finer so-called kitchen Apples, rendered positively insipid by sugar of inferior quality or otherwise. Cox's Orange Pippin should be cooked and eaten without any addition whatever, and the perfume and flavour will be found vastly superior to anything in the form of cooked Apples. It only needs a trial in the kitchen to esta-

lish its supremacy as one of the best and most useful Apples ever admitted to that department, and as soon as it is found that it is not only cheaper, but better to grow sugar and flavour, than to purchase the one from the grocer, and the other from the chemist or confectioner, such Apples as Cox's Orange Pippin will be grown in thousands of tons for cooking and preserving. D. T. FISHER.

[Mr. Turner, of Slough, informs us that this Apple was raised by Mr. Cox, of Lawn Cottage, Colnbrook, in 1830. Of two pips of Ribston Pippin, sown in a pot by Mr. Cox, one turned out to be Cox's Orange Pippin, and the other Cox's Pomona, both remarkably fine Apples. These Mr. Cox gave to Messrs. E. Small & Son, nurserymen, Colnbrook, in 1836, and they were sent out by that firm four years later. Cox's Orange Pippin was awarded a Queen Adelaide medal at a show of fruit held in St. James's Hall, as the best flavoured Apple in the show. The growth of the tree, which has small foliage, is slender and graceful. Our plate was prepared from specimens of this Apple grown in Mr. Dancer's garden at Chiswick, on trees grafted on the French Paradise stock soon after the discussion which took place respecting it some years ago. They have yearly borne abundant crops of large fruit, bright, and excellent in flavour.]

Pruning and Training Gooseberries.—It is said that in Guernsey the cultivation of Gooseberries is particularly well understood, that the Gooseberry bushes, or rather trees, when standards are pruned so as to keep them quite hollow in the middle like a cup, and that this facilitates the growth and ripening of the fruit, and also the picking of it. Is it not a fact that Gooseberries bear to the end of the youngest shoots, and consequently that there would be a manifest gain in growing them like espaliers, where they could be run out to any length? An old-fashioned green Gooseberry, which, when ripe, had a flavour like that of Violets, appears to be extinct—at least, I am not aware that it is ever seen in Covent Garden Market, and it has disappeared from private gardens. It was a very round Gooseberry, and neither large nor hairy, but I have never known its equal in flavour, although, like my neighbours, I have lost it for many years. It was an abundant bearer.—A. [When Gooseberry bushes are grown as standards, the Guernsey method of cultivating them by pruning the centres of the bushes well out is excellent both as regards ripening the fruit and freedom in gathering it. When Gooseberries are grown on espaliers, they can be pruned by spurting the young shoots, when the fruit on them will get very large and fine for dessert; but where quantities are required for tarts or for bottling, it will be found best to grow them on standards. The leading young shoots on the branches of the bushes grown in the form of espaliers will not, of course, want spurting in until they reach the length required. The old-fashioned green Gooseberry which "A" says had the peculiar flavour of Violets may have been the Green Gascoigne, a variety now nearly out of cultivation. There is another old sort, the Pitmaston Greengauge, a smooth and very high flavoured kind, and now not so much grown as formerly, for both it and the Green Gascoigne are too small for market purposes.—WILLIAM TILLERY, *Welbeck.*]

Fruit v. Malaria.—Residents in the Western States of America, and other regions where intermittents and similar diseases result from malaria, state that a regular supply of ripe, home-grown fruit is almost a preventive. Eat the fruit only when fully ripe, and only moderate quantities at a time. Good hardy fruits, and of kinds that bear early and are fertile, should be planted out on every new place, as indispensable to health as well as to comfort and economy, and emigrants to new countries should take a supply with them, as the best medicine chest they can provide.—J. J. THOMAS.

The Ribston Pippin in Nova Scotia.—The old Ribston Pippin, one of the best of dessert Apples, is cultivated quite extensively in King's, Annapolis, and Hants Counties, Nova Scotia, and on a clayey loam comes to good perfection. The tree is not a vigorous grower, and is rather a shy bearer, but bears more or less every year. The fruit is often in perfection in February and March, so we learn from the report of the American Pomological Society.

To Prevent Nails from Rusting.—Nails used for fastening shoots to brick or stone walls soon rust and break, unless prevented by some previous preparation like the following:—Before using the nails, heat them red-hot, then throw them into cold linned oil; this will give them a coat of varnish, and preserve them from rusting and becoming brittle.

Fruits of Orange Growing.—At Philadelphia, in Fulton Market, and at various places in Central New York, the common sweet Oranges of Florida have been sold at 4s. per dozen, when Oranges from the West Indies and from the Mediterranean were selling at 1s. per dozen. I have no hesitation in placing the present annual average income derived from easily accessible groves in full bearing at £200 per acre. I know instances in which this rate has been greatly exceeded. It is advisable, however, for the producer not to expect a net income of more than £100 per acre—100 trees to the acre, 600 Oranges to the tree, and 4s. per 100 for the Oranges above the cost of production.—F. P. FISHER.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vines and Red Spider.—The plant louse, generally but erroneously called red spider, although it does not increase quite so fast as green fly, is even more injurious to plants than that pest, particularly such as have soft leaves, like the Vine or the Peach, and its effects are not only of a most serious nature during the spring season, but also during the ensuing summer. If proof of this were needed I might point to the way in which it injures the growing crop of Grapes when the leaves of the Vines that bear them have been allowed to become only partially affected; so apparent is this that even in the case of strong vigorous Vines that are not over-cropped, the fruit will always be found to lack colour if spider has been permitted to establish itself on the foliage for a short time only before it is ripe, and its weakening influences are always perceptible in the ensuing season, even if the leaves have not been affected by it until after the crop has been gathered. In thus pointing out the effects produced by those (to the uninitiated) insignificant, but nevertheless certain destroyers of plant life, I am simply giving a note of warning; for, in such seasons as the present, when all outside vegetation has been retarded by the unprecedented continuance of ungenial weather, the result always is that the weakened vitality of plants of all kinds that are subject to the attacks of these pests induces them to appear in larger numbers, and that too often before their presence is suspected. This will be found to be the case, especially with Vines under glass that were subject to spider last year. Water, both in the shape of moisture in the atmosphere, and still more when applied by means of the syringe directly to the leaves, is the best preventive; and as I have before urged, although it has a tendency when it reaches the fruit through the syringe, to impair the bloom upon the berries, it is still much better for amateurs to use it than to follow the more approved practice adopted by experienced Grape growers. I should therefore recommend its daily use after the fruit is set until the crop begins to colour, applying it both to the under and, as far as possible, to the upper sides of the leaves, so as to moisten the whole, also keeping the atmosphere humid by throwing water about on the paths, walls, and on every other available surface. Not only is this necessary for the purpose in question, but also for assisting the berries to swell up to their full size. That peculiar condition of this fruit when developed to the highest point and described as hammered is never present when there has been any deficiency of moisture in either the atmosphere or the soil. An insufficient use of water to preserve the requisite amount of moisture in the air may be said to be almost a general failing in the case of amateurs' Vineries. Beginners and those who have not had considerable opportunity of seeing the effects produced where enough moisture in this way is used whilst the crops are swelling until the time the berries begin to colour, can form no idea of the difference in size and general appearance when their requirements are thus fully supplied; this, together with giving air in the mornings just as the sun comes upon the glass to warm the internal atmosphere a little, coupled with the all-important operation of closing early in the afternoons so as to shut in plenty of sun-heat, has the effect not only of perfecting and hastening the maturity of the present season's crop, but also the equally important point—the ripening of the wood for another year, without which, no matter how good the condition of the Vines in other respects may be, it will be useless to look for fruit. There is no fruit that amateurs who possess a glass structure of any description are so fond of as Grapes, and none in which they take so much interest in cultivating; but to succeed, especially where little or no fire-heat is employed, it is at all times necessary to attend to the directions given above, particularly during such an exceptional spring as the present.

Peaches.—Under glass, where no artificial heat is used, or so little as to merely bring them in a few weeks before those on the open walls, will now require attention as regards still further thinning the fruit; it is best to do this at different times, going over the trees and removing some at short intervals. In this operation amateurs are liable to make mistakes; it is not alone the removal of the superabundant fruit that is required, but the retention of those that are placed best and have the necessary room to come to maturity. Where the trees are grown on walls, and where there is enough in quantity to select from, never leave any that are placed on the back of the shoots, that is, betwixt the shoot and the wall, for in such positions they evidently cannot have room enough to grow. As far as possible, let all that are retained be directly in front of the shoots, where they can have nothing to interfere with full development, and where they stand in a situation to receive the full influence of the sun. Syringe diligently every afternoon during all stages of the crop, from the time the fruit is set until it begins to colour, not merely sprinkling the trees, but giving them a liberal application so as to wet the whole surface of the leaves; if this be

assiduously attended to, its effects will not only be the production of large handsome fruit, but also a clean, healthy condition of the trees, that augurs well for the coming season's supply.

Pits and Frames.—Cucumbers and Melons grown in the old-fashioned but still useful manure beds will have had a hard time of it for many weeks past. Not only has the comparative absence of sunshine been a serious drawback to healthy growth, but the continued prevalence of strong cold winds has made it difficult to keep up the requisite temperature, still further aggravated in cases in which the beds have occupied cold, unsheltered situations; during such weather repeated linings of new hot fermenting material are indispensable, and these should always be applied before the heat has got too low, and a sufficient amount of the material should be used, or the heat cannot last long. When the weather has become milder, Grass mowings from lawns, if possible, mixed with half their bulk of last autumn's gathered leaves, will be sufficient to maintain the requisite amount of warmth. Cucumbers in the earliest beds should be kept well thinned out, removing all shoots that are in excess of what are needed for bearing purposes, remembering that it is much better to keep them somewhat thin than to overcrowd. It is a great mistake to allow a confused mass of entangled growth to be formed with the certain result of its having to be removed after it has contributed seriously to exhaust the plants. It is an easy matter to keep the same plants going for a considerable portion of the season if they receive timely attention in thinning; this can only be accomplished by going over them every week, and removing all growth that will not be required as soon as it makes its appearance, always, after the plants have attained a moderate size, pinching off the shoot immediately beyond where a fruit shows itself, and, in the case of freely bearing kinds, considerably reducing the number of the shoots; along with this, it is indispensable to syringe daily with tepid water, not merely just damping them overhead—a process by some thought to be sufficient—but giving the leaves a thorough wetting, getting to their under surface as much as can be done, without which it is impossible to keep down insects. Never at any time of the year use cold water; if possible, let it be considerably warmer than the soil of the beds. Plants that have been bearing some time will now be benefited by liberal applications of manure-water every week, not using it too strong. Whatever is used in the preparation of this, whether it be guano or farmyard manure, a little soot is an essential addition; it not only assists in invigorating the plants, but it is distasteful to animal life of all kinds. If, as recently recommended, fermenting manure has been prepared for making up Melon beds whereon to place spare frames that have been used for bedding plants, these will shortly be ready for the plants, which, if sown and potted on as suggested some weeks ago, will be in a condition for turning out as soon as the soil is in a fit state for planting them. Thus managed, they get a considerable start compared with smaller plants, which is important, as the time they have to grow and mature their fruit leaves nothing to spare. The plants in the earlier made-up beds will be fast swelling off their fruit, and should receive a sufficient supply of water. Syringe them freely every afternoon, but in this, as well as in applying it to the roots, the collars of the plants should not be wetted more than can be avoided, as many of the more tender kinds are liable to go off at that point, especially when grown in frames, a complaint much more frequent now than it was a considerable number of years ago, and which is aggravated by either the base of the plant, or the soil around it being wet.

Flower Garden.—Bedding plants that have been planted out should receive every attention in order to induce them to grow freely, cover the beds, and produce flowers in the least possible time. The untoward weather which we have experienced has hitherto prevented much progress being made in bedding out, and if all be not done to further the growth of the plants, the cold nights of autumn will be on them before much display has been made. See that all subjects of a straggling habit, such as Verbenas, Heliotropes, Ageratum, and Petunias, are at once pegged down as soon as they are planted out, otherwise they get blown about and broken, and the collars of the plants get injured. Another source of injury, and in some cases a portion of the plants dying off without apparent cause, is an insufficiency of water; in small sprinklings without the mistaken practice exists of applying it in small stratum in which the roots are; than this nothing can be more certain to produce failure. The more tender plants, such as Iresines, Coleus, Alternanthera, and subjects of a similar character, should now be planted out if the weather be warm and settled; but in this, as in most other gardening operations, it is anything but good practice to be guided by a particular date. Even if the time has arrived for doing a certain thing, if the weather be not suitable, it is much better to wait for a more favourable opportunity.

Conservatories.

Much difficulty is generally experienced in keeping up a sufficient amount of atmospheric moisture in the above structures at this season, without causing a certain amount of discomfort by wetting the pathways or foliage of plants immediately contiguous thereto. To obviate this as much as possible, the borders and any hidden parts under the stages or among the pots should be well damped at the time of watering the plants, which operation should be performed at the most convenient part of the day, when the house is least likely to be visited. Taking the welfare of the plants into consideration, the proper time for such work during the summer months is in the evening, as then the water has time to soak well into the balls of earth, thereby benefiting the plants to the greatest extent, and filling the sap-vessels before fresh demands are made upon them. Where *Camelias* are planted out, or have to remain permanently in conservatories, they should now be well syringed at least once a day, to counteract the exhausting effects of a dry state of the atmosphere. Unless they are well attended to in this respect, they are sure to get out of health, or become infested with small white scale, which is one of the most troublesome insects to get rid of, as it can only be removed by hand-washing.

Passifloras, *Tacsonias*, and similar roof-climbers will now be growing most rapidly, necessitating frequent attention in thinning and regulating the shoots. These never look better than when allowed to hang gracefully down from the girders, thinly clothing the roof of the house, that its architectural beauties may be seen to advantage. Roofs of such structures, draped lightly with foliage in this way, are far more pleasing and effective than if the climbers be allowed to become a crowded and entangled mass. The distance at which the shoots should be left from each other will depend in a great measure on the kind of conservatory the plants are grown in, and the amount of light that can be admitted to the occupants beneath them; but, taking the appearance of such climbers as *Passifloras* alone into consideration, they show off to the greatest advantage when left about 1 ft. apart. The borders in which these are growing, if at all of limited extent, must now receive abundant supplies of water, to make up in some measure for the small quantity of soil the roots have to feed upon. Liquid manure, if made from guano or soot, or some other strong fertilising agent not likely to give off an offensive smell, may be used with great advantage; and, if given frequently during the growing season, the plants may be kept in health and vigour for many years.

Lapagerias are now making their young growth, and if in properly-drained borders, with plenty of rough, peaty soil, they can scarcely have too much water for the next three or four months. In their native habitat they grow and bloom during the rainy season, when the sky is constantly overcast, thus clearly indicating the kind of treatment necessary to cultivate them successfully. Taking the natural conditions as a safe guide, it points equally to the necessity of growing them in shady positions, and keeping the atmosphere moist, or where this cannot be conveniently done, the plants should be frequently syringed, which will help to keep down scale and thrip, insects they are rather subject to, especially if grown in a house where the air is at all dry and ungenial. Any that are growing unsatisfactorily, through defective drainage and sour soil, should at once be examined and remedied, as they will bear transplantation or any disturbance of this kind better when growing than at any other time. In lifting them for the purpose of adding fresh drainage, the close inert soil must be forked carefully out from the roots, the greatest care being taken that they be not bruised or broken. Soft, porous brick, or broken pots is the best material to be employed for drainage, and should be 6 or 8 in. at least in depth, with from 2 ft. to 2½ ft. of rough lumps of peat and sharp sand resting upon it. To prevent the drainage from becoming blocked, fresh cut peaty turves should be laid over it, and, except for filling in among the roots, any other that is added should be in the same state, to ensure proper and lasting porosity. The operation should be carried out as quickly as possible, that the plant may not suffer from the roots becoming dry or the top flagging, to counteract which syringe freely overhead, at the same time keeping it well shaded till it starts again into growth.

Habrothamnus elegans.—This is one of the most useful and showy plants it is possible to have, either for training on walls or growing in the bush form in pots to decorate conservatories or greenhouses. Planted out where it has plenty of root-room and a temperature in winter ranging between 45° and 55°, it will flower continuously and almost as freely at that season as at any other time of the year. It is, perhaps, never seen to better perfection than when trained to a wall and allowed to form plenty of breast-wood, as then every shoot stands well out and arches gracefully, laden with rich glossy clusters of flowers. To assist them in giving a constant suc-

cession of these any old growth that has ceased blooming should at once be cut back, leaving an inch or two at the base to form a kind of spur from which the wood will start and replace the portion removed. Any that are becoming exhausted should have a portion of the old soil removed to be replaced with a mixture of fibry loam and rotten manure, in which they will soon root and grow with great freedom. Being gross feeders they will require plenty of manure-water when carrying a heavy crop of bloom, and it likewise will have a good effect in keeping the leaves a dark healthy green colour. As a pot plant it is equally valuable, and, with a little management as to resting and pruning-in, it may be had in bloom at any season desired. Cuttings struck now and grown freely on during the summer will make useful-sized plants for winter flowering, when they can be brought gradually on as required by subjecting them to a little artificial heat. When grown in pots they must be liberally fed and have plenty of root-room, or the leaves soon assume a sickly appearance and fall off at the lower end of the branches.

Chorozemas will now be going out of bloom, and should be well thinned by cutting away that portion of their growth that has borne flowers, in order to admit of that now forming being laid in its place. For the present this should be allowed plenty of freedom, as any bending of the young shoots to tie them down to a trellis, or train them in any formal way, would greatly impede their growth. As soon as they begin to start freely they should be shifted on into larger pots, using rough peaty soil, and fibry loam, in about equal proportions, after which they should be placed in the warmest part of the greenhouse to complete their growth.

Azaleas will now be at their best, and should be kept in cool, well-ventilated houses, so as to prolong their season of blooming to the utmost extent. Dryness at the root soon cuts short their beauty, an arid state of the atmosphere has the same effect, therefore both must be guarded against as much as possible. The immense number of blooms well-grown *Azaleas* usually carry is a great tax on the roots, and unless these are kept well supplied with water they fail to respond to the active demands made on them; and if the supply fail but once, the plants soon relieve themselves of their burden by shedding their blooms. If they are confined to moderate-sized and well-drained pots, it is almost impossible to over-water while they are in flower and making fresh growth. Keep the air of the house well charged with moisture by damping well under the stages, or any other available surface.

Fuchsias.—Autumn or spring struck plants of these should be shifted on as they continue to fill their pots with roots, using for the purpose, good fibry loam in a rough lumpy state, to which should be added about a fourth of sweet, mild manure, such as may be obtained from old Mushroom beds. To induce them to break back freely, the points of the lateral shoots should be nipped out, and occasionally it may be necessary to serve the leader in the same way, that the plants may be regularly furnished with side branches from top to bottom, so as to make handsomely shaped pyramids, in which form *Fuchsias* always show to the best advantage. Where it is required to have any early in bloom, they should have less shade and atmospheric moisture afforded them, which will soon harden the young wood and hasten the desired result. On the other hand, where free growth is wanted, the plants should be kept well syringed and moderately shaded, till they have attained the requisite size, when they may soon be had in flower by resorting to the above treatment. Any that have filled their pots with roots will be greatly benefited by being watered with weak liquid manure once or twice a week, or even more frequently, as they get well forward in bloom.

Pelargoniums, of both the show and fancy kinds, ought now to be liberally assisted in the same way. Where any of these are confined to very small pots, they may with advantage be placed in shallow pans to ensure the roots being kept well supplied till the plants have discontinued blooming. The Zonal varieties should be kept well up to the light to induce a firm short-jointed growth, without which they go too much to leaf and do not flower at all freely. A pit or frame suits them best at this season, as they can be fully exposed by withdrawing the lights whenever the weather is favourable. When growth is nearly completed this adds much to their flowering capacity by the hardening effect it has on them. The double *Pelargoniums* especially, usually so strong, gross, and sappy when grown under glass, are greatly improved by being subjected to the above treatment, by which their growth is much moderated and their blooming proportionately increased. As these are much more valuable after the show and fancy kinds are over, the flowers should be picked off that the plants may for the present be kept growing on and make the finer display when more wanted. Many of the Zonals make useful winter bloomers if struck now and kept free from flowers during the summer so as to rest until late, when a little dry heat will speedily bring them on.—J. SHEPPARD, *Woolverstone Park*.

Orchids.

At this season some difficulty is generally experienced in keeping the temperatures of the different houses at the right point, some days being warm enough to permit fires being dispensed with, while other days, and the nights generally, are too cold to warrant such a course being followed, even in the case of the Odontoglossum-house; great care is therefore required in only keeping sufficient fire-heat raise the thermometer to the required point, for if the temperature, by means of fire-heat, be allowed to get too high, it necessitates the introduction of too much air, and even this does not remedy the evil: for although, by giving air, &c., the thermometer may be kept almost down to the desired point, there will be a dry, consuming heat in the house that will not nourish vegetation, but, on the contrary, exhaust it. The fires should, therefore, as I have said, be carefully regulated so as to maintain only the necessary amount of heat, and should be allowed to slumber, as it were, or go quite out on warm sunny days, starting them again in the afternoon. If there be no fire-heat in a house, it signifies but little whether the temperature gets even 7° or 10° higher than that recommended or not, but too much fire and sun-heat together is very bad for the plants. The regulation of the temperature can be managed by checking the flow of hot water by means of valves, with which the heating apparatus of every Orchid-house should be furnished. The matter in that case would not be left entirely to the firing. Attend to the keeping up of moisture in houses in which the plants are growing by throwing water about under the stages and syringing the back walls. See that the shading is properly attended to, and wash over any part of the glass, where the blinds do not meet, with whitewash with some linseed oil poured in it; it will then adhere as firmly as paint, and be easily removed when no longer required.—JAMES O'BRIEN.

Hardy Fruits.

After more than a fortnight's continuance of easterly winds, the force of which at times has amounted to a gale, whilst the maximum nightly reading of the thermometer has never exceeded 35°, and has several times been as low as 28°, it cannot be wondered at that fruit prospects are anything but bright; certainly for the time of year such weather is most extraordinary, and, fortunately, unusual. However, we must hope for the best, and take such prompt steps as will insure the health of the trees, and the preservation of such fruits as have passed the trying ordeal by destroying aphides, which abound, as is always the case, during the prevalence of easterly winds. The garden engine or hose should be freely used to dislodge them, and if sopsy water be used, say twice a week, for three weeks successively, the trees will remain clean for the remainder of the season. Soap-suds, and clear water applied with force afterwards, are the best antidotes for those kinds of aphides which, more or less, at this season, attack Peaches, Cherries, Currants, and sometimes Plums. On light soil watering will now be necessary, but on heavy retentive soil, if the ground be mulched to prevent cracking, this will not be necessary. Peaches, Apricots, and Strawberries cannot well have too much water at their present stage of growth, that is, unless the drainage be in an imperfect condition; and it should be remembered that one thorough watering is worth many dribbles. Strong crowns of Strawberries that have thrown up a large number of flower-stems should have the weaker ones removed; this will increase the strength of those that are left, and the fruit will be much finer in consequence. When the flower-stems are freely thinned, fine fruit is insured without thinning out the fruit separately after it has set: they should never be allowed to get dry, for no fruit suffers more or sooner from drought. The fruit of Apricots, Peaches, and Nectarines should now be finally thinned; it is a mistake to defer this operation till the fruit is stoning or stoned. I have always observed that the fruit has successfully passed this critical period if it had been thinned as soon as well set, and the opposite in every case when the fruit was left till the stoning was complete. The excessive quantity of fruit usually formed makes impossible demands on the tree for nourishment; hence failure, to a certain extent, must ensue if not previously thinned. The new growths or shoots of Peaches and Nectarines that are intended for fruit bearing next year will shortly be sufficiently long to be laid, tied, or nailed in, in doing which, see that each shoot has sufficient space for perfect development of leaf and bud. Strong-growing terminal shoots should be pinched back somewhat closely, when they will break into two or more growths, one only of which should be allowed to remain, the others being stopped at one joint, and if growth still continue strong, pinch again. It will now be safe to remove all superfluous shoots from Pears, Plums, and Cherries, but previous to this all the young wood required to refurbish bare places on the walls should be nailed in. Cordons should have their terminal shoots secured to the walls, and the side-shoots stopped to a couple

of joints. Bush and pyramidal trees may be pinched in to a more or less number of joints, according as the trees require furnishing, or the shape they are desired to assume; in any case growth should not be allowed to go at random, according to the new plan now being advocated by some.—W. WILDSMITH, *Heckfield*.

Trees and Shrubs.

The cutting and barking of Oak timber is now the most important work in progress. We began here on the 25th April, about a week or ten days later than usual, the weather having been very unfavourable for bark peeling. North-easterly winds and frosty nights have continued intermittently since the commencement, causing a check in the flow of sap, and the foliage on many trees is beginning to assume quite a sickly colour, while the young leaves are curling up through the extreme cold, so unusual at this time of the year. The Oak copses and plantations here are under a systematic course of management, being thinned every fourteen years, averaging about 140 or 150 acres annually, the yield of bark being from 80 to 120 tons. The past three weeks of cold, dry weather, having been a trying time for recently planted trees and shrubs of large size, attention should therefore be paid to these by applying a liberal supply of water, and having the surface over the roots covered with a thick layer of litter. All planting operations should be finished by this time, with the exception of Hollies and Evergreen Oaks, which can be safely removed and started into growth at once, but their roots must not be exposed to the air for any length of time, watering freely head and roots when planting. The past season for forest and ornamental planting has been the most favourable time I ever experienced. We began here in October and planted on without any intermission (except for about a fortnight through the frost and snow) until the end of April. Referring to my nursery note-book, I find that we planted out 77,300 Larches, 4 ft. to 6 ft. high; 7300 Conifers, 3 ft. to 7 ft. high; 26,000 Hardwoods, 5 ft. to 7 ft. high; 200 Hardwoods (Park trees), 15 ft. to 25 ft. high; and about 1400 deciduous and evergreen shrubs; altogether upwards of 112,000 plants. From a recent examination, I conclude that there will not be more than five per cent. of loss throughout the whole. In forming these new plantations, pits for the reception of the plants are dug from 5 ft. to 6 ft. apart. The Hardwoods are not planted until after the Larch, but Laurel boughs or shoots are distributed in the holes at from 12 to 15 ft. apart previous to the planting of the nurser to represent the Hardwoods, the Laurel shoots being counted before distribution; by this method a correct account of Hardwoods required can easily be ascertained, and the arrangement of the masses and the judicious disposal of groups can be better managed after the nurser are planted than before. I use nothing but the Larch as nurser for Hardwoods; it does not take up so much room as evergreen Fir, allows a freer circulation of air, and is, in fact, the best and most profitable plant for such a purpose. If shelter be required I prefer planting a screen or strip of Pines on the most exposed sides—Austrian, Corsican, and Scotch Pines are the most suitable, the former on the outside, as it excels all others as a shelter tree, filling up with Scotch Pine as nurser. If game cover be required Silver or Spruce Fir, planted in clumps and filled up with Larch as nurser, answer the purpose better than indiscriminate planting. I plant the Hardwoods of each sort in distinct, irregular-shaped, sectional masses, according to the nature of the soil and exposure. The old-fashioned plan of planting indiscriminately, probably a dozen or a score of different sorts of trees over an acre of ground regardless of soil or situation suited to the different trees, cannot be too strongly deprecated. In disposing of the different sorts of Hardwood I plant masses of Beech and Sycamore on poor land and on exposed sites; next to these Wych Elm and Sweet Chestnut, and, in the best land and most sheltered situations, Lime, Oak, and Ash. For the sake of ornamental and landscape effect Purple Beech is introduced in clumps amongst the common Beech, the Norway and Red Maple amongst the Sycamores and Sweet Chestnuts; and groups of the White and Lombardy Poplars and American Scarlet Oak amongst the Oak and Ash. The system I adopt here to ensure almost certain success in planting operations is to buy two or three-year-old plants from the nurseries and grow them on in our private nursery, shifting them every two years until they are large enough to plant out. The Larches that were planted out this season averaged about 5 ft. high, with the stems nearly as stout as walking-sticks, and fibrous roots like those of pot plants. The Hardwoods averaged about 7 ft. high, with clean stems and good leaders, having all undergone nursery pruning, and none of them having stood longer than two years without moving. The park trees had stout stems 3 in. or 4 in. through, with well-balanced heads, and roots—a mass of fibres like door-mats. Another reason why success is pretty certain—they are lifted one day and planted the next, the roots never being allowed to get dry. Wherever extensive forest and ornamental planting is carried on a home nursery is almost indispensable.—GEORGE BERRY, *Longleat*.

THE INDOOR GARDEN.

NATURAL HABIT v. TRAINING AND STAKING.

WITH nearly all plant growers now-a-days, it is a foregone conclusion that their specimens, whether for exhibition or not, must be trained into some kind of artificial shape. An Azalea, or a Rose, both of which naturally make handsome bushes, are unworthy of commendation, and quite unrepresentative at an exhibition, unless they represent a cone or a pyramid of the most exact proportions. Pelargoniums must be as regular as a gridiron, and as flat as a pancake. Heaths, Epacris, and similar hard-wooded plants are nothing unless they bristle with stakes, and are as round as balls; and graceful climbers and creepers are twisted in the shape of balloons and other accommodating models of a similar kind. This is no exaggerated picture, for it is one which may be seen at every horticultural exhibition. Ornamental-foliaged plants set the trainer, in great measure, at defiance; but when he can improve them, as he terms it, he does so. I have many a time seen such plants as *Alcousias* and *Caladiums* with every leaf staked out in the most methodical way; but usually such plants escape, and, whether on the exhibition table or in the hot-house at home, compensate in some degree for the stiffness and formality which would otherwise be only too apparent. Horticultural exhibitions are most to blame for this state of things. The plant grower, however humble, goes to them for his models, and seeing that the largest and most perfectly geometrical specimens have been awarded the first prize by a jury of eminent horticulturists, he thinks, and quite naturally too, that it is imperative for him to follow the example there shown, and even endeavours to increase its formality. People are, however, beginning to get tired of such stiffly-trained plants, and if some good plant grower had only the courage to stage a collection of healthy plants, exhibiting, as far as is practicable in artificial culture, their natural shapes, one can hardly suppose that a jury of sensible men would venture to overlook them. Of course, one need not run into an opposite extreme and renounce the use of stakes and ties altogether; nor would I suggest a disregard to symmetry in the case of plants which naturally assume a definite form; but I protest against the style of training which sets natural habit at defiance, and which insists that every twig and flower be twisted about and tied till they are arranged in such a way that a single bloom could not be removed without creating a blank. I have seen *Ixoras* that would have been noble bushes, twisted about in all manner of ways in order to have the flowers in the form of a cone; Heaths, with their naturally erect tops twisted hither and thither, that no spot should be unoccupied—one flower being up, and another down; Epacris with their wreaths of flowers plastered round a bundle of stakes as tight as a drum; *Maréchal Niel* Roses with all their blooms fixed immovably to one side; and many other subjects, too numerous to mention, similarly abused—just in proportion to their obstinacy or otherwise in conforming to the cultivator's art. Of course, rambling plants must be supported in some way, and others must be staked or trained out to increase their size, to admit air and light, and to accommodate them generally to the circumstances in which they are placed; but, after this has been accomplished, what more is wanted? A *Pelargonium*, if rationally treated, will make a handsome enough bush without much artificial aid; and, singly or in collections, it will produce a more attractive display than when trained in the shape of a circle, with scarcely a green leaf visible. The much-abused *Azalea*, too, needs hardly any training at all. It will grow just as shapely as a *Rhododendron* in the open border, and be as healthy, and flower as well, or better, if left alone: and staged, where and how one will, it will afford quite as grand a display, and be ten times less monotonous, than the finest pyramid that ever was grown, and on which months of patient but useless labour have been bestowed. Then there are the *Epacris* and *Aphelexis*, which need no stakes or ties whatever. Perhaps they may not be "furnished down to the pot;" but, if they get light, and room, and generous treatment, there will be healthy foliage, wreaths of flowers in abundance, and nothing to complain of in the matter of shape or symmetry. No one finds fault with the

habit of the *Rose* as it grows in the open border; why, therefore, should it be tortured out of its natural shape when grown in a pot? Soft-wooded Heaths will bear cutting down to get good, stout, flowering shoots, but they want but little more assistance; while the close-growing, hard-wooded varieties certainly do not require a perfect forest of stakes to keep them either in shape or good health. Camellias, too, are sometimes trained like Azaleas, in the pyramid fashion—a most inexcusable practice, for does not the *Camellia* grow of its own accord as freely and as shapely as a *Laurel* bush? As to climbers, such as the *Clerodendron*, *Stephanotis*, *Allamanda*, *Bougainvillea*, *Cissus*, *Plageria*, and others, it might reasonably be maintained that there is no excuse whatever for twisting them round stakes, trellises, or other contrivances of that kind, except to meet the necessities of exhibitors. The natural habit of such plants is to ramble at length like our *Honeysuckles* or *Virginian Creepers*, and it is only under such conditions that they can be seen to advantage, and grow most successfully and with the least trouble. In short, the artificial training of pot plants, carried as it is to excess, is the one great mistake in their culture at the present day, and must sooner or later give way under the influence of improved taste. To those who have no other desire than to see their plants healthy and handsome, we would say—give up training after the formal pattern; give your plants room, and light, and air; attend more to potting and watering, instead of staking and tying; and you will have no cause to complain of ill success, and will in time come to wonder that you were ever led away by the practices just described. S. W.

PASSION-FLOWERS.

THESE, on account of their singular beauty and the associations connected with them, are popular plants with most people. *P. cœrulea*, the hardiest and best known, is a pretty variety which grows and flowers freely on open walls, and in favourable situations ripens its fruit. It does well between the gables of two lean-to glass houses, for example, or on the sheltered end of a cottage with a fire behind it. It likes a moderately light, rich, loamy soil, and if the roots be enclosed on all sides with slates or flags, and not allowed to get down too deeply, they will be much more favourably situated as regards temperature, watering, and general culture than they otherwise would be. How to train it is a consideration, and the simplest plan is the best. It is a mistake to nail the shoots up or across the wall, as is usually done. If the wall be not very high, lead the main limb up to the top direct at the beginning, and then along the top just under the coping. Most likely it will throw out side-shoots as it grows; but, if not in sufficient number, occasional pinching will make it break more freely. The shoots should simply be allowed to hang down on the face of the wall without tying of any kind, and a very graceful drapery they will make, either with or without flowers; but flowers are sure to be produced in quantity. The extension system of training is the best in the case of *Passion*-flowers. We have seen a lofty-fronted glass structure, 70 ft. long, draped from end to end with them in the manner just described, the shoots being allowed to fall 9 in. apart. Two plants furnished the whole, one being planted out at each end. The culture of greenhouse varieties is pretty much the same as for the hardier kinds. In all cases it is well to confine the roots in a stone box, from 2 ft. to 4 ft. wide, according to the area which the plant has to cover. If practicable, train also in the same way. Take the shoots along the roof in a methodical manner, but let their extremities hang down here and there in order to bring their flowers within reach, and to give the plant a natural aspect. If the roots be well drained, water freely and often, as they soon fill a large box, and get as matted as in a flower pot. Top-dress, too, annually or periodically with rich soil, and additional root-room will never be required. I once had a plant of *P. edulis* which bore a heavy crop annually for many years, the roots all the while being confined to a box 20 in. square. During the growing season the knife must be used freely in order to remove entirely the shoots where they are too crowded; and, when the plant ceases to grow and flower as winter approaches, it should be pruned well back to the

old wood. Stove varieties, such as *P. Buonapartia* and *quadrangularis*, may be treated the same as the greenhouse sorts when grown for the sake of their flowers, but, if fruit be the object, more careful and slightly altered treatment is necessary. *P. quadrangularis* and *P. edulis* are the two kinds that are most esteemed for their fruit. The first is the large and now pretty well-known *Granadilla*, and the second has fruit about the size of a pigeon's egg, purplish coloured, and the more ornamental of the two; but both form an agreeable addition to the dessert. I have had fifty or more half-pound fruits on a plant of the *Granadilla* which was struck from a cutting the previous autumn. Cuttings of the young points should be struck in summer or autumn, and early in February they should be planted out in a 20-in. pot or tub in a good compost of loam, leaf-mould, and manure, and plunged permanently in a bottom-

prune the shoots hard back, and keep the plants still, but moist at the root, all the winter. Almost all the varieties are subject to red spider and mealy bug; but generous culture and a vigorous application of the syringe will generally keep both these pests in subjection. The best stove kinds are *P. amabilis*, *Belotii*, *kermesina*, *edulis*, *princeps*, *quadrangularis*, and *Buonapartia*; the greenhouse sorts consist of *Innesii*, *Impératrice Eugénie*, *racemosa*, *cœrulea*, and *Campbellii*. J. S.

ARALIA ELEGANTISSIMA.

THE foliage of this new and handsome *Aralia* is of a deep green colour shaded with brown, the mid-rib of each leaflet being white. The stem is erect and furnished with digitate leaves on long, dark green foot-stalks, which are mottled with white; the filiform leaflets, being

Aralia elegantissima.

heat of 85° or 90°. As the shoots grow rapidly, they must be prevented from becoming entangled, and be trained within a foot of the glass, and never stopped on any account. If they get crowded, remove some of the shoots entirely, but allow those left to grow on uninterruptedly. About midsummer flowers will be produced towards the extremities of the shoots, and they will continue to appear afterwards at almost every joint; as they expand daily, they must be fertilised with a camel's-hair brush, or they will not set. Maintain a moist and high temperature throughout the growing season; 75° by night and 90° with sun-heat will suit them well. When the fruit begins to change colour, diminish the moisture a little, but at all times keep all the supply at the root, for the abundant foliage makes a great demand upon the roots, and if water be not supplied in abundance the fruit will drop, especially in the early stages of its development. About November, when it is all gathered,

pendulous, impart a very graceful character to the plant. It has been imported from the South Sea Islands, and is a remarkably effective ornamental foliage plant. Examples of it in good condition have been shown on several occasions by Mr. Bull.

RAISING GLOXINIAS FROM SEED.

SOME sow seed of Gloxinias every year so as to have always a stock of moderate-sized roots, and also because young plants are supposed to be the most vigorous, which is perhaps true; but when the object is simply to have plenty of plants with little trouble, and also an abundance of flowers large enough for all practical purposes, the best plan is to keep the roots in stock, and repot them annually in successive batches, so as to prolong their flowering season. When the roots get very large they will bear dividing and sub-dividing, if care be taken to secure a bit of the crown with each piece. I have some

old plants now which were thus treated. They were potted in 6-in. and 7-in. pots in February, and they measure now 18 in. or more across, and are fairly smothered with fine flower-buds just beginning to expand. I attach no importance to the size of the flowers, for moderate-sized ones are in every way the most useful for cutting, and they look as well as large ones on the plant. When seed is used it should be sown in March, but there is still time to have good plants before winter by sowing now. Sow in a well-drained pan, using a light and fine compost of loam, peat, and sand, in equal parts. The surface of the compost should be made fine and even, and the seed should be sown regularly and thinly, and barely covered over. Set the pan in a warm stove temperature near the light, and do not water for a few days after sowing, and sparingly at all times, for though *Gloxinias* like a moist atmosphere, they do not care to be drenched at the root, being like *Gesneria* in that respect. When the seedlings are fairly up, and can be well handled, pot them off in the same light, rich compost as before, and take care not to injure the tender leaflets, which are easily broken. Keep them throughout the season in a genial stove temperature—the back shelf of a Pine stove is a good place for them—and they should be placed near the light, shading them from bright sunshine, which is apt to brown the foliage. As winter approaches, and when the plants show signs of maturity, gradually withhold water, and let them dry off at the root and go to rest, when they may be stored away in their pots on a dry shelf in the stove or potting shed, but they should never be subjected to a temperature much below that of the stove in winter, or they will be apt to rot—the fate of all tuberous-rooted tropical plants under such circumstances. When the tubers begin to sprout in spring they should be shifted, using pots according to the size of the roots, and they should be introduced again to the stove; but it is better to withhold water for a time until they have fairly started, when it may be given, and continued when required during the season, as before directed. I always put the plants in their flowering pots at the beginning, as there does not appear to be any advantage in shifting them on, and, besides, the foliage is almost sure to get injured by handling.

CHIEF.

Thawing Plants.—Mr. Peter Henderson speaks against the popular treatment of placing frozen plants in the shade and sprinkling them with cold water, as being quite insectual, if not injurious to them, and mentions the following circumstance as one of several that has induced this belief. During a mid-winter blustering night the thermometer sank to 12° below zero, and, in spite of all the efforts of himself and men, thousands of plants in the greenhouse were more or less frozen. The following day one of the houses was well shaded and the plants treated to cold water. The other houses were not shaded and the plants were not watered, with the result that more plants were destroyed in the former than in the latter.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Succulents at Regent's Park.—Mr. J. T. Peacock has forwarded to the Royal Botanic Gardens, Regent's Park, a choice collection of *Agaves*, *Aloes*, *Cacti*, and other succulent plants, which will remain there as a permanent exhibition. They are now in progress of arrangement in the new wing, which is to be opened by the Duke of Teck, on the 1st of June next.

Removing Camellias.—I have some Camellias that have been planted out about two years, and which I want to remove about 60 miles by train; would the present be a proper time for the operation?—*Marsden*. [It is a little too late; Camellias are best just when they have ceased blooming, and before they have begun to make new growth.]

Succulents in Flower.—The following are now in good condition at Sudbury House, Hammersmith, viz., *Echinocactus concinns*, *Willamisi*, *antractosus*, *submammosus*, *terribilis*, *lopholepis*, and *hexedrophorus*; *Mammillaria ubiformis*, *cirrhifera*, *recurva*, *Peacockii*, *Roeziana*, *glochidiata*, *viridis*, for its name, *Widdiana*, *pumila*, *stellata*, and *Fischeri*; *Cereus tuberosus*, *Malesoni*, *leptopus*, *fragilliformis*, and *speciosissimus*; together with various *Phyllocacti*, *Gasteras*, and *Haworthias*.—*J. СВОУСЛЕД*.

The Scarlet Windflower (Anemone fulgens).—This makes an effective pot plant—that is, if several roots be placed in a good-sized pot. The foliage is stout and handsome, and the flowers, which are intensely scarlet, rise well above it. Exhibitors of hardy flowers in pots should look after this *Anemone*, because it possesses a richness of colour that by no means common amongst hardy plants. Its time of blooming may also be regulated by the time when the roots are planted, and whether they are kept under glass, or placed in the open air. As a border plant it only needs to be known to be generally cultivated.

Common Toddax (Linaria Cymbalaria) as a Window Plant.—If a graceful trailing plant be required for a hanging basket or bracket pot inside a sitting-room window, I know of none better than this; for, in addition to slender pendent growths, clothed with a small dark-green Ivy-like foliage, it bears pretty little Snapdragon-like rosy purple flowers in the axils of the leaves, and it is fresh-looking and in bloom during the summer and winter, if plentifully supplied with water. It grows best in turfy loam, intermixed with lumps of sandstone grit, and more luxuriantly in a shady window than in a sunny one.—*B.*

ENGLISH FLOWER GARDENS.

FASHION, which exacts such frequent changes in all that relates to our social life—in our dress, in our domestic architecture, even in the time and place of our holidays, and in other such matters—is singularly constant in respect of our flower gardens. For more than forty years we have hardly moved. About that time ago it was that fashion decreed that an Englishman's pleasure-garden should only be bright for three months in the year. His trim Box and Yew hedges had long before been voted out of date and cut down; his topiarium triumphs, his urns, and his peacocks and his monkeys quaintly carved out of Evergreen trees, had been laughed at; his old English flowers, his Canterbury Bells, Sweet Williams, and Columbines; his Pansies and Gillyflowers, whose very names are sweet and racy of old English song and story, were rooted up and cast away. When the ground was clear, and the gravel paths had been neatly turfed over, on the level expanse of green were cut beds of singularly inartistic shape, square, circular, oblong, trefoil, slug-shaped, and caterpillar-shaped, arranged in more or less of symmetrical order. Into these unlovely receptacles, when the frosts of spring were over—that is, in the middle of May—a greenhouse full of *Geraniums*, *Calecularias*, *Cinerarias*, *Lobelias*, *Heliotropes*, *Fuchsias*, and *Verbenas* of various shades of colour, were hastily stuffed, there to make the best fight they could against our inclement climate. If all went well, if the east wind were not too much for them, or the rains excessive, the plants got into fair blossom in about six weeks, and into full bloom in a fortnight more. In a month afterwards, there was the beginning of the end; the less persistent bloomers were going off, the *Heliotropes* often were cut down by the frosts of September, and by the middle of October the garden was a wreck. From that time till the May following, that is, for a whole seven months, there was no garden at all, only the bare earth of the beds—the places where the flowers "were not."

The innovation which I have above described in the past tense most faithfully represents the present state of the garden system of ninety-nine English country houses out of a hundred. All that we have done to enlarge its narrow bounds has been the weak attempt to introduce the so-called sub-tropical gardening, which is often little more than a development of the same system of wintering tender plants under glass, and planting them out for the short summer; and then again we have invented the more successful and effective foliage-plant gardening, the use, that is, of *Colens*, *Pyrethrums*, and others; this, of course, also requiring the use of the greenhouse during the cold months, and being only a further development of the same artificial mode of plant culture. I seriously urge that this prevailing style of garden is wrong in principle, very uninteresting, quite inartistic, and as compared with the effect produced, extremely expensive. Wrong in principle, because, while the object of a garden is to give us constant pleasure, to be what the poet says a thing of beauty is, "a joy for ever," the modern English garden, assuming (which I deny) that it is a "thing of beauty," is a "joy" for hardly three months out of twelve. Wrong in principle, because, when summer is with us, and every bank and hedgerow are delightful with green plant-growth and gay blossom, and we could best dispense with a garden, then only it is that we have one. In the dull winter and early spring months, "when fields are mire and ways are foul," when we can often not go into the lanes, and by the meadows; when we want to be cheered by the pleasant sight of well-filled flower-beds, our garden with its damp and spongy turf, and its empty beds, bare and naked as newly-made graves, is about as inspiring a sight as a London churchyard. Wrong in principle, because the original object of making the garden gay in autumn, was, that its owners, coming from their summer sojourn in London, should enjoy, on their return, the bloom of their flowers, without having assisted at their struggles into luxuriance. But apart from the fact that not one country family in ten who have gardens spends the season in town—apart from this, our habits have changed. Most of us now pass these very two or three months at the seaside, or abroad, or in visits to country houses, and often never see a *Verbena* or a *Geranium* of our own in perfect flower.

The result of such gardening is inartistic, because, while the beauty of flowering plants is threefold—their colour, their form, and their variety—their colour alone is utilized in our English system. The only object of the gardener is to get together as many masses of bright colour as he can; he pegs his plants down to cover the ground, and is melancholy if a single patch of bare earth be visible. The plants are too much crowded for their form to be seen to advantage; and as to variety of growth in leaf, branch, and flower, as to all the matchless and cunning redundancy of Nature's handiwork, all this is lost. There can be none of this variety in our gardens, because the list of so-called "bedding-out plants," that is, those which will admit of being planted out in

May, and that will grow vigorously and flower freely, is limited; it hardly comprises a dozen species. Moreover, to harmonise the few garish colours employed on a green expanse of turf, is a task from which even a good artist might shrink. The gardener seldom dreams that there is such a thing as colour-harmony, or that a bright yellow *Calceolaria* near some tender blue flower, a scarlet and a pink *Geranium* close together, an orange *Gazania*, and a blue *Lobelia* in close proximity, are not quite lovely combinations of hues. It will take very little eloquence to persuade owners of gardens thus maintained that the expense of them is very great. Greenhouses are not built, warmed, and kept in repair for nothing. To carry out the "bedding-out" system with any sort of completeness and success, demands skilled labour of no light kind. A modern English gardener requires an education which is nothing less than scientific, and, as every one knows, his salary in large establishments is higher than that of many professional men. In mere material—seeds, flower-pots, tools, garden-engines, tobacco for fumigation, and new plants—the cost is considerable; and all this to produce a result which is ludicrously disproportioned to the outlay. The English and, worse still, the Scotch climate, is certainly not such as a man would choose for gardening in; but a bad climate has something to do with the making of a good gardener—it forces him to fight it. The English gardener has a high repute all over Europe; the Scotch gardener is confessedly the best in the world. The worse our climate the more need indeed have we for pleasant gardens; the duller our winters, the chillier our springs, the shorter our summers, the more occasion have we to refresh our eyes with the gay colouring of flowers, to catch the sunshine on south walls, to rear lofty bulwarks of greenery against the sharp north winds, and to prolong the summer blossoms of our flowers. There are immense difficulties in the way of doing all this, but it is not for Englishmen to shrink from them. It is not for us, because "it is hard to conquer" these obstacles, to consent to shrink them—to say "the English climate is so absolutely insufferable that we only condescend to expose our flowers to it for four or five months; the rest of the year they must be boxed up in a glass house." The time was when our gardens were perennial, like the plants that filled them, when every season had its growth and its interest, its bloom and its attraction.

Elizabethan Gardens.

Let us see how a garden was regarded at that period of our history, when English wits and English taste were confessedly at their brightest and best; let us see what sort of a thing an English garden was in the generation in which Elizabeth reigned and Shakespeare wrote. Here is a description of one by a man who was considered the foremost statesman, the greatest lawyer of his century, one of the most perfect of courtiers and the wittiest man of his day, and whom posterity has recognized as the chief of England philosophers. Here is Lord Bacon's idea of what a garden should be:—"God Almighty first planted a garden; and indeed, it is the purest of humane pleasures. It is the greatest refreshment to the spirits of man; without which, *buildings and palaces* are but grosse handy-works; and a man shall ever see, that when ages grow to civility and elegance, men come to *build stately*, sooner than to *garden finely*, as if *gardening* were the greater perfection. I doe hold it, that in the royall ordering of *gardens*, there ought to be *gardens* for all the *months* in the year: in which, severally, things of beauntie may be then in season. For *December* and *January*, and the latter part of *November*, you must take such things as are greene all winter: holly, ivy, bayes, juniper, cypresse-trees, eugh, pine-apple-trees, firre-trees, rosemary, lavender, periwinkle, the white, the purple, and the blew: gormander, flagges, orange-trees, limon-trees, and myrtles, if they be stooved, and sweet mariorum warme set. There followeth, for the latter part of *January* and *February*, the mezerion tree, which then blossomes; crocus verus, both the yellow and the gray; primerooses, anemones, the early tulippe, hyacynthus orientalis, chamairis, frettellaria. For *March* their come violets, specially the single blew, which are the earliest; the yellow daffadill, the dazie, the almond-tree in blossome, the peach tree in blossome, the cornelian-tree in blossome, sweet-briar. In *April* follow the double white violet, the wall-flower, the stock-gillyflower, the cowslip, flower-delices, the lillies of all natures; rosemary flowers, the tulippe, the double piony, the pale daffadill, the French honny-suckle, the cherry-tree in blossome, the dammasin and plum-trees in blossome, the white thorn in leafe, the lelacke tree. In *May* and *June* come pincks of all sorts, specially the bluish pincke; roses of all kinde, excepte the muske, which comes later; honny-suckles, strawberries, buglosse, colombine, the French mary-gold, flos Africanus, cherry tree in fruit, ribes figges in fruit, raspes, vine-flowers, lavender in flowers, the sweet satyria, with the white flower; herba muscaria, liliun convallium, the apple tree in blossome. In *July* come gillyflowers of all varieties, muske roses, the lime-tree in blossome, early peares and plummies in fruit, ginnit-

ings, quaddings. In *August* come plummes of all sorts in fruit, peares apriocokes, berberies, fiberdes, muske melons, monks hoods of all colours. In *September* come grapes, apples, popies of all colours, peaches, melo-cotones, nectarines, cornelians, wardens, quinces. In *October* and the beginning of *November* come services, medlars, bullises, roses cut or removed to come late, hollyhokes, and such like. These particulars are for the *Climate of London*, but my meaning is perceived that you may have *Ver Perpetuum*, as the place affords."

The gardener of to-day may well smile at the enumeration of some of these "Things of Beautie;" the "Piggos in fruit" would hardly fit into any modern system of flower gardening, but Bacon was as large-minded in his gardening as he was in his philosophy, and would have his garden to contain every fruit and flower that serves for man's use and pleasure and refreshment. His garden would cover, he says, not less than "Thirty acres of ground," and be divided into three parts: a *greene* in the entrance, a *heath* or *desart* in the going forth; and the *maine garden* in the midst; besides *alleys* on both sides. And I like well that four acres of ground be assigned to the *greene*, six to the *heath*, four and foure to either side, and twelve to the *maine garden*. The *greene* hath two pleasures: the one, because nothing is more pleasaunt to the eye than *greene grasse* kept finely shorne; the other, because it will give you a faire alley in the midst, by which you may go in front upon a *stately hedge* which is to enclose the *garden*. But because the alley will be long and in great heat of the year, or day, you ought not to buy the shade in the *garden*, by going in the sunne thorow the *greene*, therefore you are, of either side the *greene*, to plant a *covert alley* upon Carpenter's work, about 12 ft. in height, by which you may go in shade, into the *garden*. A garden was thus to be a place where a man could take his pleasure, not a piece of decoration to be taken in by the eye at a glance, and then to have no further interest. He would have no meretricious appeal to the sense of sight, and, oddly enough, he anticipated the most rational of the objections which have been made to the system of the great French gardener, Le Nôtre, who flourished under Louis XIV., and whose leading notion was a tracery of various complicated designs in Box, in stone, and in coloured sands, on the surface of the ground. "As for the making," says Lord Bacon, "of *knots*, or *figures*, with *divers coloured earths*, that they may lie under the windowes of the house, on that side which the *garden* stands, they be but toys; you may see as good sights many times in tarts. Indeed, he would by no means appeal to the eye alone in his ideal garden. I know in all the multifarious writings on gardening nothing that betokens so intense a love of flowers, and so intimate a knowledge of them, as the following passage:—"And because the *breath of flowers* is farre sweeter in the aire (where it comes and goes like the warbling of musicke) then in the hand, therefore nothing is more fit for that delight, then to know, what be the *flowers* and *plants* that doe best perfume the aire. Roses, damask and red, are fast flowers of their smell, so that you may walke by a whole row of them, and finde nothing of their sweetness; yea, though it be a morning's dowe. Bayes likewise yield no smell as they grow; rosemary little; nor sweet mariorum. That, which above all others yields the *sweetest smell* in the *aires* is the violet; especially the white-double-violet, which comes twice a year; about the middle of *April*, and about *Bartholomew-tide*. Next to that is the muske rose; then the strawberry leaves dying with a most excellent cordiall smell; then the flower of the vines—it is a little dust, like the dust of a bent, which grows upon the cluster, in the first coming forth. Then sweet briar; then wall-flowers, which are very delightful, to be set under a parlor, or lower chamber window. Then pincks and gillyflowers, specially the matted pinck and clove gillyflowers. Then the flowers of the lime-tree. Then the honeysuckles, so they be somewhat a farr off. Of boane-flowers I speake not, because they are field flowers. But those which *perfume* the aire most delightfully, not passed by as the rest, but being trodden upon and crushed, are three: that is, burnet, wilde-time, and water-mints. Therefore you are to set whole alleys of them, to have the pleasure, when you walk or tread."

I have not space to quote more of this delightful essay to show how "the garden is best to be square; incompassed on all the foure sides with a *stately arched hedge*;"—how "*fountains* are a great beauty, and refreshment; but *pooles* marro all, and make the *garden* unwholesome,"—how the heat is to be a natural wildernes, the side grounds filled with a "*varietie of alleys*" to give shade, and "for shelter when the wind blows sharpe;"—but I have given enough to show the general idea of Lord Bacon's garden, and to let the reader see from how poor a catalogue of plants this grand garden was to be furnished. Since those days of the "early tulippa," and "sweet satyria with the white flower," we have certainly made great and numerous acquisitions of flowers that will open bravely to our suns; and great blame is due to us if, having them, we fail of doing what Englishmen succeeded in achieving three hundred years

ago. From the reign of Elizabeth to the middle of the last century, the fashion of our English gardens was copied from the Italians, who loved and still love fountains, terraces, low balustraded walls, broad stone-paved paths, beds filled mostly with flowering shrubs, "stately alleys," embowered retreats, and great walls of close-clipped Horn-beam, Box, and Yew; adorning this pleasure with statues, and with architectural decoration of temples, alcoves, and porticoes; now we would copy from the French, whose style of gardening is all this stiffened and formalised, and without the Italian richness of line and breadth of lights and shadows; or again, from the Dutch, who cut and torture their evergreens into quaint shapes of men, monkeys, peacocks, and elephants—who love straight lines and rectangular paths and flower-beds, and replace fountains with fish-ponds, and terraces with stagnant canals. All these varieties of gardens found their admirers and imitators in England, but it was not until the period when philosophers of the emotional kind, like Jean Jacques Rousseau, were beginning to discover that all formal laws were a mistake, that Nature was the best guide in everything, from ethics to the nursing of babies, it was not till this period that some of our English writers began to apply these great principles to gardening, and to discover that we had all along been constructing our gardens in a radically unphilosophical manner; that we had been appealing to art, and that we must now appeal to Nature.

A More Natural Style of Gardening.

The new school of philosophers cast aside all tradition and all law as alike false, artificial, and oppressive; and the new school of gardeners followed suit. A straight line was a line drawn by a slave, a flower-bed with two sides that corresponded was an utterly base and unworthy thing. The disciples of the new philosophy were bidden to seek out Nature, to consult her, to watch her various moods, to copy her effects, to reproduce her smoothness in their lawns, her ruggedness in their rock workings, her picturesque and sinuous curves in their flower-beds and walks; to mass their Laurels and Rose bushes as she massed her trees in the primeval forests where the desecrating hand of man had never been laid; to mark how she grouped the eternal hills, and to arrange their flower-pots in the same tumultuous disorder. These fine principles resulted in what is sometimes called the "picturesque," and sometimes (offensively enough) the "gardenesque" style of landscape gardening. Abroad it was known as the "English style," and its leading idea falling in with the prevailing fashion for unsophisticated nature, it quickly found many admirers and adopters. The high priests of the new religion in England were Lancelot Brown and Sir Uvedale Price, a Herefordshire country gentleman, who wrote a book and carried the principles contained in it into forcible execution whenever he could. He was a true enthusiast in the matter, and no doubt as tedious to his friends as most enthusiasts. When he was elected High Sheriff of his county, it was spitefully said, "Price will want to group his javelin men!" But Sir Uvedale was a scholar and a man of some latent taste, and he lived to deplore the excess of his zeal. The other famous "naturalist" was Brown, known as "Capability Brown," who treated the face of Nature as a painter does his canvas. His idea was to get the land to be like the picture of some fashionable landscape painter. He sat down at a "point of view," and recomposed the landscape; felling an old Oak tree here, planting a group of tall Poplars there, raising a hillock in the middle distance or levelling an inequality in the foreground, carrying the waters of a horse-pond into a hole in the middle of the lawn, because Claude or Poussin had a pond in the corner of a particular picture, cutting down a wood and letting in the east wind, to make a "vista," and otherwise deforming the sweet face of the country side. At this day very few people believe in the "noble savage" theory and the "religion of sentiment," but the school of gardening which was founded on the development of these grand theories still flourishes. It is, on the whole, the prevailing style in which English gardens are laid out to this day.

Gardens in naturally Picturesque Localities.

I can recall many gardens and garden grounds in naturally picturesque localities, where advantage has been taken of wood, rock, lake, or ravine, with most admirable results. One such garden in the Highlands of Scotland is particularly in my recollection. Here a path winds along the side of a precipitous rocky bank overhanging the mountain stream below. The gardens follow the path; now a narrow rim of bright flowers, as the rocks close down upon the pathway, now broadening into a border with flowering shrubs, now opening out into a level bit of garden plot, and diversified at each step of the way by the ever-changing views of rock scenery, Pine forest, and waterfall. In another garden in Ireland, where a broad lake is within a stone's throw of the house, the islands lying thick on its surface are connected with the shore and with each other by

light wooden bridges, and are all laid out in garden beds, with their rich green turf intersected by paths of shining white gravel. A third such garden I can recall—the most beautiful of all—in a foreign country where most of our common greenhouse plants grow in the open air. Here also the ground is rocky and intersected by deep ravines. The broad walls are covered over with trellis-work, which holds up a matted growth of Roses, the tea-scented Adam Rose and the Cloth of Gold Noisette being predominant; Bignonias, the Plumbago capensis, and several species of Bougainvillea, Passion-flowers, and Tacsonias. On the sun-exposed rocky ground, the Scarlet Geranium and the Prickly Pear mingle curiously; and Fuchsias, Heliotropes, and various species of red and yellow Hibiscus, the Poinsettia, and other such plants, grow into large and free-flowering shrubs. The watercourse below is mantled with a thick growth of Arundo donax, the great spear-like Reed of warm climates, and the broad-leaved Caladium. In such situations as these it would be a desecration of Nature to level the ground, to build walled terraces, or to make rectangular paths; but in a country where the surrounding scenery is without attraction in itself, where it is barren and yet not picturesque, or, on the other hand, highly cultivated and tame, or where the space is limited and shut in by walls or houses—there the eye rests delightedly on the rich luxuriance of a cunningly devised design in the Italian style, on terraced walks, arcades, fountains, quaint sundials, and balustrades of grey Lichen and Moss-covered stone, on broad expanses of smooth gravel, separated by rims of moulded stonework from the deep velvet of the turf; and all this contrasts again with the still deeper green of the clipped Yew hedges, against which the marble statues show white and glistening, and the drops from the water jets sparkle like diamonds. What a setting is such a garden as this for flowers! How their rich hues come out doubly rich, and their colour-harmonies doubly tender and doubly harmonious! This is gardening for millionaires. The work must be the best of its kind; not necessarily elaborated or highly finished, but true art-work, with the hand and mind of a master visible everywhere. Men of modest means must be careful how they try to make a sham garden in this style, with painted plaster casts for marble statues, and instead of rich marble or stone balustrades, a pitiful imitation in painted wood, with rubble walls cement-covered to make them look like stone, and similar abominations.

Imitations of Nature Condemned.

This brings me to the enunciation of another important canon in gardening art—a rule which if the reader apply to other things than gardening, he will be none the worse a man. Nothing about a garden should pretend to be what it is not. The strict application of this rule will, of course, give the death-blow to artificial rockeries, or roteries, to those abominations of imitation in common use—iron half-hoops for path edging made to look like bent sticks, to imitation rains, and to all the various shams we have indicated above. If with a due observance of this rule a man choose to practise economy, if he make judicious use of the materials accessible to him, never attempting to pass a thing off for that which it is not, never trying to paint a brick to look like a stone, or a bit of iron-work like a stick, he may still produce admirable results. For a moulded stone edging worked by the chisel he may substitute square tiles of a light colour set edgewise [an abomination!—ED. GARDEN]; his terrace wall may be of dark red brick, unpainted, and he may with perfect propriety promote the growth of Lichen and Moss upon it by occasional watering with a muddy water. Such a wall, so treated, loses its "stairness" in a year, and in a decade is a lovely object. On its top, in lieu of balustrade or open work, he may set three or five rows of roofing tiles transversely, the hollow side down, and the rich effect of pierced work is obtained at once and quite legitimately. Instead of using stone or marble vases, he may plant his clipped Laurels in wooden tubs, as the gardeners at the Tuileries and the Luxembourg used to do with their Orange trees; and a Portugal Laurel so treated—barring flower, scent, and fruit—is nearly as ornamental as an Orange tree. [Why put a tree in a tub which may be grown much better planted in the ground?—ED.] Statues he must, of course, not think of, nor indeed do they will become any garden but a very grand one. Moreover, a second-rate statue is a painful object, and it is perhaps in questionable taste to employ statues at all in this climate. An undraped marble figure in a March wind is a shivery object, and our summers are perhaps not long or hot enough, nor on the whole are our æsthetic developments sufficiently pronounced, to allow us really to enjoy the sight of the heathen gods and goddesses,

All standing naked in the open air.

But if our climate make statues in doubtful taste, there are other quite legitimate non-floral adornments. Sun-dials are, it appears to me, the most fitting and charming ornaments that a garden can possess. In our dull climate particularly, when the sun will not

show for days, the dial in our garden seems to be a constant reminder to us of bright weather, to be a standing protest against dull cloudy skies, and an appeal for sunny days. With their curious tracery of cabalistic line and "Zodiac sign," and their quaint Latin mottoes, the ancient dials in Dutch and French gardens are delightful objects, often true works of art. Their legends—"Horas non numero nisi serenas," bidding us forget the dark hours of life; and "Vera loqui aut tacere," Truth or silence—are full of most wholesome rustic moralising and suggestiveness.

I have hitherto said a good deal about the garden itself and very little about the plants which are to grow in it. The reader will have gathered that the present writer's opinion is that the flowers should have the rich setting of an Italian garden, and this whether the "bedding out" system be adopted, or the natural system of having flowers all the year round, or a compromise between the two. Of the "bedding out" system I mean to say nothing; so exhaustively is the subject treated in contemporary garden literature that it would be difficult to edge in a new idea. I am quite against the system, I have said why, and I now leave it alone. In the compromise between the two systems which I advocate, "bedding out," in the limited sense of taking a plant from a greenhouse in May and putting it into a garden bed, would have no place, the beds would already be full. But assuming that a certain amount of skilled labour and a certain amount of greenhouse space are available for flower garden purposes, I should propose to utilise them in a way which I shall presently proceed to explain. Our garden would be perennial; and we must first take stock of our floral possessions. When we come to compare our list of available hardy flowering plants and shrubs with the curiously restricted catalogue at the disposal of the gardener in the sixteenth century, it will be seen that we are positively embarrassed by our wealth. Even Lord Bacon's list is largely made up of importations from abroad; and since then the four quarters of the globe have been ransacked for hardy as well as for greenhouse plants.

The gardening of every nation should, and indeed must, be made subservient to its own circumstances and surroundings. An English garden, with its absence of shade and its turf-sower-beds, would be dried up and baked the colour of toast in a week under the sun of Spain or Italy; and such gardens as dwellers under southern skies enjoy would speedily become the habitation of the newt and frog, if transferred to northern climes. In Russia, open air gardening is only a very sorry makeshift, and the "poor frozen-out gardeners" of the North have to conduct most of their operations under glass; and on a very magnificent scale they do it, enclosing under a huge glazed dome a whole garden plot, with its parterres, walks, arbours, and fountains. This sort of thing has of late years been much recommended for us, but we have not quite come to that yet, and gardening, to keep the hold it has on the likings of English men and women, must continue to be an out-of-door occupation.

The fashion in gardens in Southern Europe has always been for shade and for coolness. Here is a short description of a garden, written some two thousand years ago, which I translate:—

In thick-leaved Elms the breeze is whispering;
The cooling waters of a sacred spring
Drip from their rocky source, and from near by
The thrushes sing and the cicadas cry.

This is a perfect picture of the only sort of garden which is enjoyable in a hot climate: the shade, the light breeze, the cool splash of water, the pleasant sounds of Nature. Such are the gardens of Greece, Turkey, Southern Italy, and Egypt. The ideal of an Arabian garden is a dense shade of Plane and other broad-leaved trees; and so thick are their groves of sweet-scented shrubs that a garden is rather a wood than the open space which we make our garden pleasancess. Here water is for ever heard dropping into marble basins, and the moist air is heavy and faint with the sweetness of Orange flowers and Musk, Roses and Jasmynes. This somewhat exaggerated liking of the Arabs for excessive shade and moisture was, I suspect, carried to whatever lands in Europe and Africa their civilization reached. In Morocco, in Spain, and in Sicily, this Arab or Moorish type of gardening is still found. In the Peninsula a proverb runs, "a garden without water, a house without a roof, and marriage without love, are all bad things;" and first, it will be seen, on the black list is put the waterless garden. In the suburbs of a certain ancient city of Spain there is an old Moorish garden of this sort—a most enchanting spot. Coming from the dusty street without a single step brings one into a fresh cool atmosphere that might have given its former Moorish owner a foretaste of his Moslem paradise. Among other modes of bringing the freshness of the water to the senses, among various ways of multiplying its sound and sight, among devices for causing threads of water to fall from a height into brimming fountains and water-spray to glauce in the light, was one which the writer had seen nowhere else. A broad flight of marble steps

leads from the upper to the lower part of the garden, and the marble-trade on either side of these steps is topped by flat slabs of marble, along which a narrow channel is cut, and down this there constantly flows a tiny rannel of clear water; at each landing-place and at the bottom of the stairs an earthenware jar is let into the marble, and the water flows into and out of it with a spiral whirl and a gurgling sound. The notion may seem a fanciful one to us at home, where the splashing of the rain-drops and the gurgle of water is no variety, and one requires to be a little baked and dusted in a country where the rain often holds off for five months, before one can appreciate the pleasure of dipping one's fingers into running water as one walks up and down stairs. Charming as these Moorish gardens are they would of course, be stupid enough in this country, and we Englishmen have exceptional difficulties to contend against. In the south there is the dry, sun-baked air to cool and moisten; in the north, the obstacles to gardening are snow, ice, and excessive cold. We have both extremes to fight against—heat in summer, cold in winter, in addition rain and cloudy skies at all seasons. Beyond all doubt, therefore, our task is a harder one than that of gardeners in the ice-bound north or in the sunny south. We cannot make our gardens one huge greenhouse, like the Russians, nor one mass of shade, like the people of Southern Europe. If, then, we abandon our present garden system—and there are signs and tokens of such abandonment—to what shall we betake ourselves?

It is essentially a question of taste and of custom. As our national taste enlarges, and as it gets educated into real culture, so I believe shall we get to be dissatisfied with a garden system which, though it has pleased us during nearly two generations, is, nevertheless, thoroughly narrow and thoroughly un-English; but there is a far more serious aspect to the question than that of good or bad taste. A garden is more than a mere recreation—"a refreshment to the spirits," as Bacon calls it; it is an important means of health. A garden swept by the cold sleety winds of winter and spring, dank and spongy underfoot, tempts us forth indeed in ungenial weather, but it tempts us to our destruction. It is thus that the seeds of fatal disorders are sown—it is thus that colds and chills and sore throats begin, with all their long and often fatal sequences.

It is the opinion of the present writer that we are on the eve of a great reform in gardening. Social revolutions come about, as a rule, not because sensible people see and expose the defects of the existing order of things, but because conventional people get in time tired of their own conventionality, and sigh for a change. A garden system which costs a great deal, which makes a short, garish, and vulgar show, an imposture which satisfies no artistic taste, cannot hold its own in the England of to-day, where a sound aestheticism is gaining a certain hold upon all classes, and where shams are happily getting every day to be thought more and more ridiculous and degrading. I therefore confidently predict that a new order of gardening is at hand, and that the established English garden will soon be a thing of the past.

[We reprint the above portions of an essay on English flower gardens from "Country House Essays," by Mr. John Latouche, because while interesting in various ways, it is also more than usually free from the ignorance of our art so often displayed by writers on horticulture in the Reviews. It, however, is not free from the common error, expressed in an offensive manner, that all gardeners hate hardy plants. Thus, in speaking of the Christmas Rose, we are told that it is "no doubt, despicable enough in a professional gardener's eye." This kind of talk is untrue and very unjust, for it is to gardeners—and the best gardeners—that we owe the preservation of our collections of hardy flowers through the years of neglect from which they have of late been emerging. When in nearly every private garden in the land orders to adopt bedding-out in all its severity were given, and the old flowers were consigned to the rubbish-heap without a protest, who saved our precious collections of hardy flowers? Why, mainly nurserymen, independent enough to have their own way in spite of fashion—the Backhouses, Hendersons, Osborns, Lawsons, Wheelers, and the botanic gardeners like Moore, McNab, Niven, Bain, and others. Saturday Reviewers and all other writers are quite welcome to fill their pages with abuse of bad gardening and bad gardeners, but a wholesale abuse of gardeners is most foolish. Mr. Latouche, in a passage we have not printed, holds the Italians to be masters in the art of garden design, and that the example they have set us is best to follow. Having gone through Italy from north to south, with a view of seeing what Italian gardens were worth following, we cannot agree with him on these points. The Italians made such gardens as great artists and architects might be expected to make on hilly ground. Their style is the worst and most costly that could be adopted for the mostly level gardens of England. The men who formed the style adopted it, like clear-headed creatures, to the places where they lived and worked. Mr. Latouche has also an

original notion as to the substitution of glazed covered ways "along sunny southern walls," with "movable shutters" in front, "thick canvas" &c., all of which seems to us no improvement on a good airy orchard house, Camellia house, cool conservatory, or covered way—though some may prefer his way. On one point, however, we think he will have very little support, and that is, the substitution of broad paved or graveled pathways for "spongy turf." Gardens are certainly not now deficient in graveled pathways, and he is no friend to the garden who would remove a yard of turf for a yard of pavement. Convenient and well-drained walks we must have, of course; but the needless "cutting up" of our beautiful carpets of turf all garden lovers should protest against. With these remarks, we welcome Mr. Latouche as an advocate of progress in the art of gardening.—Ed. GARDEN.]

The White Butterwort (*Pinguicula alpina*).—This is now a charming plant on our rock-work, its clear, white, compact blossoms contrasting beautifully with the dark shady rocks, in the fissures of which it grows. For years we have lost many of this species every winter, the few survivors leading us to believe that it was the most difficult of the genus to cultivate. Now we think it the easiest. The fault lay in our ignorance, not in its constitutional "unfitness for our climate." *P. alpina*, unlike its allies, has strong, deep-rooting, branching, brownish, fibrous roots, which fix themselves tenaciously among smashed granite, or other hard stones, mingled with a very little peat and sand (three-fourths stone). Grown in this way it thrives most vigorously, even in pots, shaded from the sun and in a rather humid position.—J. BACKHOUSE, *Tork*.

Ornamental Hedges.—In a recent number of THE GARDEN one of your correspondents mentions (see p. 461) a hedge which was made of wild Roses, Clematises, &c. I am anxious to make an ornamental fence to part off my garden, and the hedge mentioned by your correspondent seemed to me to be just what I want, especially if a few bushes of cluster Roses, Gloire de Dijon, &c., were added, but I fear that the wild Rose (or Briar) would grow too much in height and not be sufficiently dense to make a good hedge. If, therefore, any of your correspondents could help me by their advice in reference to this matter I should be most grateful. The ground is open, and has lately been pasture land, and the soil is a good dark loam.—RALPH WALKER, *Ellerslie, Teleseter*.

New Ivy-leaved Pelargoniums.—Some new Ivy-leaved Pelargoniums, which have been raised by Mr. George, of Putney, have (says the "Florist") passed into the hands of Messrs. E. G. Henderson & Son for distribution. They are of free and vigorous growth, and have bold trusses of large, well-formed flowers. Their names are—Camballo, rich lilac, tinted with rose, and carmine lines on the upper petals; excellent in form, the petals overlying each other. Duchess of Edinburgh, elegant blush-white, with violet and rose twin streaks on the upper petals, and a rosy-pink blotch. Miss Blanche, soft, delicate lilac, with violet-purple streaks on the top petals; this has a neat, well-branched, dwarf habit of growth. Nemesis, clear carmine, deepening into magenta, and shaded with crimson, the upper petals pencilled with violet; flowers of fine form, and very effective. St. George, deep lilac, shaded with carmine; this is a free, vigorous habit of growth. Now that hanging baskets are so much employed in conservatories, these Ivy-leaved Pelargoniums will be found very useful.

Spot in Peach Leaves.—I should be glad if any one could tell me the cause of "spot" on the leaves of Peach trees. It does not seem to affect young leaves so much as older ones, and I find more of it on the leaf-stalk or petiole than on the blade. At first the spots are very small, but they gradually increase until they get nearly as large as a threepenny piece, when the leaf falls. At first I thought (and still think) that the roots must be at fault, but yet I see nothing wrong with them, neither has the soil been kept too wet. I have likewise suspended syringing except during sunny days, when it was done early in the morning and again towards three o'clock in the afternoon. It is only a tree here and there that is affected, others growing side by side with them and treated in the same way being perfectly healthy.—G. H.

Rust on Grapes.—"G. H. G.'s" case (see p. 485) must be an exception, as I never knew nor ever heard of rust attacking Grapes during their second swelling. In an early stage, the tissue of the skin is so tender that rust is very easily induced in many ways; cold draughts, over-heating the hot-water pipes, and allowing water to come in contact with the berries, all cause rust on the fruit, and also warts on the leaves; or sulphur, if not thoroughly cleaned off the previous year, will produce the same result: but nothing of a slight character will affect the skin of Grapes so far advanced in growth as those referred to in "G. H. G.'s" case; when the skin has become tough and leathery nothing but extremes can have any effect on it. "G. H. G." cannot, I think, have closely inspected his

Grapes in their young state, or he would have discovered the mischief of which he complains earlier.—JAMES SMITH, *Waterdale*.

My conviction is that rust in Grapes is caused nine times out of ten by the overheating of pipes that have been sulphured; but why sulphur them? As a remedy for the destruction or prevention of spiders sulphur has proved to be a signal failure, and though many assert that they have found it of benefit, I as conscientiously assert after long experience that it is worthless, and that long custom alone sanctions its use. The best remedy for spider is to keep the atmosphere, during the earlier stages of growth, moist, and continually charged with ammonia, either by means of a thin layer of stable litter (occasionally renewed) on the floor of the house, or by sprinkling the floor and walk with manure-water, or, better still, painting the pipes with guano in the same way in which sulphur is used.—W. WILDSMITH, *Heckfield*.

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE FLOWER SHOW.

MAY 19 & 20.

AMONG subjects of more than ordinary interest shown on this occasion may be mentioned the beautiful groups of pot-Roses, furnished by Messrs. Paul and Son, of Chessnut, and Mr. C. Turner, of Slough, and as if to demonstrate that really well-grown and well-arranged groups of stove and greenhouse plants are not quite things of the past, Messrs. Jackson, of Kingston, produced superb collections of both classes of these plants. Orchids were represented by well-grown collections from Mr. B. S. Williams and Mr. J. Ward, making this show altogether one of the most successful of the season, all the classes being remarkably well filled.

First Class Certificates.—These were awarded to the following new and rare plants, and florists' flowers:—

Pelargonium Zonale, Exquisite (J. Laing).—This is one of the most striking of all the bronze Zonal varieties, the ground colour of the leaf being a soft yellow, with a well-defined crenate margin, and a broad and distinct reddish-bronze zone. It promises to be useful, both for pot culture and for out-of-doors.

Pelargonium Zonale, John Jenner Weir (J. Laing).—A dwarf and distinct variety, belonging to the bronze zonal section, and, like the last, of robust habit, with a well-marked reddish-brown broad zone, on a soft yellow ground.

Pelargonium Zonale, Purite (J. Laing).—This is a double-flowered variety in the way of La Cigne, and appears to bloom quite as freely.

Caladium, Madame de la Deransaye (J. Laing).—This somewhat resembles the well-known *C. Chantinii*, but is far more beautiful, the petioles of the creamy hastate leaves, and the principal veins being of a clear, rosy, pink colour. It is a very effective variety, and well worth culture.

Viola hybrida, Jupiter Black (H. Hooper, Bath).—A well-shaped and very dark—almost black—variety, of rich velvety appearance, which will be much thought of by Pansy growers.

The following, all of which have already been described in our columns, also received certificates, viz.—

Croton Disraelii (B. S. Williams).

Woodwardia radicans cristata (B. S. Williams).

Bertolonia Van Houttei (B. S. Williams).

Polystichum lepidocaulon (B. S. Williams).

Bertolonia Van Houttei (J. Wills).

H. P. Rose Star of Waltham (William Paul and Son).

Pelargonium Zonale, Wonderful (G. Smith).

Orchids.—These were well represented, the individual plants being in most cases large and well grown. Among *Dendrobies* we remarked several ferocious examples of *D. Falconeri*, a fine species, which growers seem lately to have learned how to grow and bloom successfully, succeeds perfectly in a warm greenhouse temperature. Other *Dendrobies* consisted of *D. Devonianum*, a charming species with elegant lilac and white flowers, having a fringed lip; *D. tortile rosam*, a variety with curiously twisted lilac-tinted sepals and a primrose-coloured lip, and the golden-flowered *D. densiflorum*. The best *Odontoglossum* in the show, viz., *O. Phalanopsis*, came from Mr. J. Ward. It measured quite a yard, and was thickly studded with *Miltonia*-like flowers, white in colour and spotted with rosy-lilac. The same exhibitor had also a robust specimen of *O. Pescatorei*, bearing four long branching spikes of bloom, and a deep rosy form of Skinner's *Lycaste*, furnished with twelve fine wax-like flowers; also *O. hystrix*, a large flowered form of the *O. luteo-purpureum* type, with three long spikes of yellow, brown-blotched flowers, and a large plant of *Masdevallia Harryana*, bearing twelve of its brilliant carmine, lilac-shot flowers. Among the *Lady's Slippers* we noted a splendid plant of *Cypripedium Stonei*, with flesh-green glossy leaves and four strong flower-spikes, on one of which were five long-petaled blossoms. *C. barbatum* was represented by many varieties, and there were likewise well-flowered plants of *C. caudatum*

C. villosum, and other varieties. Among miscellaneous Orchids we may refer to a well-grown example of the rosy-lilac *Scaccolabium ampullaceum*, from Mr. Williams, who had also a well-flowered *Vanda suavis*. Mr. Ward had *Epidendrum vitellinum*, furnished with three strong flower-stalks; also a well-cultured *Odontoglossum Alexandrinum*; and a plant of *O. Bicolor*, which bore twelve tall spikes of brown-sealed, blue-lined flowers. *Oncids* were represented by well-bloomed plants of *O. sphecelatum*, *O. serratum*, and others; and we also observed two or three forms of the old but ever welcome *Laelia purpurata*, of which the variety having pure white sepals and petals and a rich purple-dark-veined lip is the best and most effective.

Stove and Greenhouse Plants.—In the class for collections of new and rare species or varieties, Mr. B. S. Williams showed a well-arranged group, in which were specimens of *Kentia Moorcana*, one of the most noble of dwarf pinnate-leaved Palms; *Polystichum lepidocaulon*, *Aralia elegantissima*; *Adiantum gracillimum*, by far the most delicate and beautiful of all Maiden-hair Ferns; *Araucaria Goldiana*, a robust and distinct variety, well suited for cool conservatory decoration; and fine plants of *Pandanus Veitchii*, *Cycas intermedia*, *Woodwardia radicans cristata*, and *Maranta Makoyana*. Mr. J. H. Ley had well-grown plants of *Cocos Weddelliana*; *Geonoma gracilis*, a species resembling the last, but even more elegant in habit; *Pritchardia macrocarpa*, a new fan-leaved kind allied to the better known *P. pacifica*; *Zamia Lindenii*, one of the most distinct of *Cycadaceae* plants, having long pinnate foliage and along serrated leaflets of the brightest green; Mr. Ley had also *Calamus metallicus*, one of the most distinct Palms in the exhibition, the young foliage of which is of a rich bronze tint, quite different from that of the older leaves, which are of a dark glossy green colour. In a well-arranged collection shown by Mr. J. Wills, we remarked the new silvery-veined *Phyllanthum Lindenii*, and a well-coloured little specimen of the deep purple-leaved *Artocarpus laciniata*. In the nurserymen's class for twelve specimens, Messrs. Jackson & Sons showed some fine *Heaths* and *Epacris*, also *Aphellex macrantha purpurea*, Balfour's *Clerodendron*, and *Statice profusa*, a dense mass of purple, blue and white flowers. Other plants consisted of *Hedera fasciculata*, *Ixora coccinea*, still the most effective of all *Ixora* for exhibition, and a noble example of the brilliant *Imantophyllum miniatum* bearing upwards of twenty fine trusses of bloom. Mr. Williams also showed in this class, and Mr. Ward and Mr. Peed in that devoted to amateurs. Mr. Harrow, gardener to H. Bessmer, Esq., Denmark Hill, had the best group of fine-foliated plants, and Mr. W. Forman, of Carlton House Gardens, Herne Hill, showed the best group of decorative plants arranged for effect. *Palms* and other fine-foliated plants came from Mr. Ley, of Croydon, and Messrs. Wright, of Lee, Kent, and some well-grown *Heaths* from Mr. Ward and Mr. Peed, while Mr. Child, Mr. Ratty, and Mr. Ward had some fine *Azaleas*. Among the twenty-six varieties we noticed *Iveryana*, white; *Maculata*, double rose; *Duc de Nassau*, semi-double, rosy-crimson; *Reine des Belges*, salmon-rose, very delicate, and distinct; *Holfordi*, semi-double crimson; *Barclayana*, single white, *Duchesse Adelaide de Nassau*, scarlet shot with purple; *arborca purpurea*, a very distinct purple; and *Criterion*, delicate rosy-salmon, with a white fringe. Mr. Harrow and Mr. Hill had the best *Camarias*, these came from Mr. Williams, who had also several good specimens of *Glechomias*; and fancy *Perlargoniums* were furnished by Mr. Turner and Mr. James, the latter having also a very attractive group of herbaceous *Calcarias*, the colours of which were very vivid and distinct.

Roses in Pots.—Those shown by Messrs. Paul and Son and Mr. Turner were so nearly equal in point of merit that in each case a first prize was awarded. In Messrs. Paul's group were *Madame de St. Joseph*, a lovely Tea-scented Rose, having creamy-white petals, flushed with salmon, in the centre; *Dr. Andry*, vivid crimson; *Madame Willermoz*, a delicate white-flowered, Tea-scented variety; *Celine Forrester*, one of the best of all yellows, with the exception of *Maréchal Niel*; *Madame Margottin*, a delicate creamy yellow; *Camille Bernardin* and *Paul Verdier*, both full, bright, rosy varieties, belonging to the Hybrid Perpetual class; and *Souvenir d'un Ami*, delicate rose or blush, with finely-shaped shell-like petals. In Mr. Turner's group we remarked well-bloomed plants of *La France*, one of the most perfect of *Roses*; *Celine Forrester*, in capital condition; *Edward Morren*, a fresh and full-bloomed variety of a bright rosy tint; and *Charles Lawson*, *Madame Therese Levet*, *Madame Willermoz*, *Maréchal Vaillant*, and others equally good. In the class for 20 specimens in 3-inch pots, Mr. Turner had the best group, in which we noticed well-bloomed plants of *La France*, a distinct, new Tea Rose, in the way of *Gloire de Dijon*, but deeper in colour; *Peace Blossom*, a delicate variety, having satiny petals of a soft rosy tint; the new white or blush-coloured *Madame Lacharme*, and a well-finished plant of *Royal Standard*, a distinct and full Rose of great merit. In Messrs. Paul and Son's collection were well-flowered examples of *Duke of Connaught*, a new, dark-vetvety, crimson-scarlet Rose of great merit; *La France*, in capital condition; *Etienne Levet*; the canary yellow-coloured *Perfection de Montplaisir*; and *Madame Lacharme*, bearing several good blooms. The same exhibitors also sent six large and effective stands of cut *Roses*, consisting of new or standard varieties.

Hardy Flowers.—Of these Mr. Parker showed, as usual, a select and well-grown collection, in which were several *Funkias*, just now the most effective of all outdoor fine-foliated plants. Among them were *P. ovata aurea*, with soft pale green leaves; *F. elegans viridis variegata* with apple-green heart-shaped foliage, streaked and margined with dark glaucous green; *F. ovata variegata*, with elegantly furrowed, dark green, silvery-edged leaves, and others. A plant of the rosy-blossomed *Spiraea palmata* contrasted beautifully with its white-flowered ally *S. japonica*;

the purple-spiked *Orchis foliosa*, too, was shown in excellent condition. A large clump of *Iris spectabilis* was also very showy, as were likewise pink and rosy forms of *Scilla nutans*, various kinds of *Globe-flower*, the white *Snowdrop Anemone*, and several *Peonies*, among which *Pæonia tenifolia* and *P. officinalis* were most beautiful. The same exhibitor had also a select collection of cut flowers from hardy plants, including *Star of Bethlehem*, *Centaurea montana*, the Hawthorn-scented *Aponage-ton distachyon*, *Veronica gentianoides*, and *Spiræas*. *Pansies*, double red-quit daisies, and a stand of show *Tulips*, were also shown in this class.

Miscellaneous Plants, &c.—Some splendid specimens of *Treo Mignonette* came from Messrs. Carter & Co., of Holborn, who had also a strikingly beautiful group of *Palms*, *Ferns*, and other fine-foliated plants. Mr. John Laing, of Stanstead Park Nurseries, Forest Hill, sent an effective group of decorative plants, in which were several new and distinct bronze *Zonal Pelargoniums*, two of the best of those being *Exquisite* and *John James Weir*. In the same collection were likewise some vigorous plants of *Sempervivum Bollii*, the curious *S. tabulariforme*, both very distinct and effective carpet bedding plants; the white variegated *Day Lily* (*Hemerocallis disticha variegata*), a perfectly hardy kind, but brighter in foliage when grown in a cool frame or pit. From Mr. Wills, of the Anerley Nursery, came a beautiful group of variegated and other fine-foliated plants, including a pair of the new carmine-veined *Bertolonia Van Houttei*, fine plants of *Drazenas*, *Begonia Chelsoni*, profusely laden with pendent orange-scarlet flowers, and several choice *Ferns* and new *Marantas*. Messrs. Rolisson & Sons, of the Tooting Nurseries, had a group of *Orchids*, *Ferns*, and succulents; among the latter we noted half-a-dozen good plants of the beautiful Californian *Echeveria pulcherrima*, a broad-leaved form, having a dense coat of silvery powder on the foliage. Mr. Parker also had an attractive group of decorative plants, and Mr. Hooper, of Bath, sent some pretty stands of seedling *Pansies*. Messrs. Dobson had examples of their new *Calcarias*, which are bright and distinct in colour, and Mr. J. Ley, of Croydon, contributed an attractive collection of *New Palms*, *Ferns*, and other stove plants. To all these exhibitions extra prizes were awarded, and also to Messrs. Dick Radcliffe and Co. for several tastefully arranged *Fern* cases and window boxes. A dozen pots of *Strawberries* in full bearing came from Mr. Bristow, gardener to George Campbell, Esq. It may be added that beautiful groups of *Palms*, *Tree Ferns*, *Cycads*, and other fine-foliated plants from the Palace Gardens were arranged with much taste in front of the orchestra, where they made an effective display.

For a full list of awards see our advertisement columns.

ROYAL BOTANIC SOCIETY.

MAY 24TH.

NOTWITHSTANDING the heavy showers which fell at frequent intervals on this occasion, this exhibition was most enjoyable; indeed, there is a freshness about the Royal Botanic Society's Exhibitions which we fail to find elsewhere—a circumstance, doubtless, in some measure attributable to the fact that the plants and flowers are arranged tastefully on turf banks, thus enabling the exhibition to be seen as a whole from more or less elevated standpoints, even when the tent is well filled with visitors. This show was by no means the best which we have seen here, there being a sameness in the appearance of the plants sent for competition, which even tasteful arrangement could not wholly obviate. The collection of stove and greenhouse plants furnished by Messrs. Jackson and Mr. B. S. Williams, nevertheless, were excellent examples of good culture, and the *Azaleas* were well bloomed, although by no means remarkable as regards size. *Roses*, in beautiful condition, came from Mr. C. Turner and Messrs. Paul & Son. *Heaths* were well represented by Messrs. Jackson and Mr. Ward, and Mr. Legge had well grown collections in the amateurs' class. The best nine *Pelargoniums*, likewise, came from Mr. Ward, and the same exhibitor obtained the first prize for half-a-dozen really well-grown *Orchids*, including one of the best plants of *Odontoglossum vexillarium* we have yet seen in a private collection. *New plants* were limited in number; that is, but few were certificated which have not been previously certificated elsewhere.

Certificates.—These were awarded to the following new and rare plants:—

Aralia Veitchii gracillima (Veitch, Williams, and Ley).—An elegant stender-habited plant, previously alluded to.

Araucaria Goldiana (Williams).

Cycas intermedia (Williams).

Croton Macaeseanum (Veitch).—A robust and effective plant, somewhat resembling *C. Hookeri* or *C. acaucubifolium*, but more luxuriant, and heavily blotched with golden-yellow on bright green ground colour.

C. Mooreanum (Veitch).—An effective variety, somewhat resembling *C. Wisemannii*, but in all respects larger and consequently more effective.

Eulalia japonica (Veitch).

Phyllanthus roseus pictus (Veitch).—A graceful stove shrub with oval white-blotched leaflets, the young foliage being of a clear rosy tint.

Rhododendron Queen Victoria (Veitch).—A beautiful orange-flowered variety of the *R. javanicum-jasminiflorum* type, well worth culture as a distinct and effective greenhouse plant.

R. Duke of Edinburgh (Veitch).—Similar in habit to the last, but having flowers of a more decided rose tint.

Osmunda palustris (Veitch).—A beautiful marsh Fern, well suited for a cool Fernery, or for pot culture in a cool and moist situation.

Bollea Lalindei (Veitch).—A singular *Pescatorea*-like Orchid, bearing dark purple flowers, the sepals and petals of which are tipped with white. It is distinct, and well deserves culture.

Cypripedium Silligerum (Veitch).—This, the largest of all the hybrid Lady's Slippers, is the result of a cross between *O. barbatum* and *O. levigatum*. It is distinct and well worth general culture.

Caladium Madame Herve (J. Laing).—A green-leaved variety, having a creamy-white centre, and conspicuous bright carmine veins.

C. Madame de la Deransaye (J. Laing).—Another larger-leaved variety of considerable merit.

Azalea indica, Jean Vervaeae (Veitch, and Turner).

Habrothamnus Newellii (Newell).—A strong-growing seedling variety, bearing large and very ornamental fascicles of reddish-crimson flowers. Useful as a conservatory or cool greenhouse pillar plant or as a climber.

Pelargonium Zonale, Marmion (Denny).—A brilliant scarlet-flowered distinct variety, with circular blossoms as large as a florin. As exhibited the plant seems rather lax in habit, but the flowers are in all respects excellent.

H. P. Rose Magna Charta (W. Paul).—A large full variety of great merit, the colour being a warm rose flushed in the centre with fiery red. It is well worth a place even in the most select collection.

Double Cineraria, Prince Imperial (E. G. Henderson).—A distinct double-flowered variety of a dark purplish-blue colour.

Double Cineraria, King Alphonso (E. G. Henderson).—A bright rose-coloured variety of dwarf, compact habit, similar to the above, and equally well suited for decorative purposes.

Pansy, Jupiter Black (H. Hooper).—A large and well-formed variety, having very dark velvet-like flowers with a golden eye.

Pelargonium Zonale, J. Jenner Weir (J. Laing).—A bronze zonal of great merit, described above.

Pelargonium Zonale, Exquisite (J. Laing).—A well-marked bronze zonal, also already described.

Hybrid Mimulus (Henderson's strain—E. G. Henderson).—Dwarf and compact, large yellow-flowered varieties heavily blotched with crimson-maroon.

Stove and Greenhouse Plants.—Of these some effective groups were exhibited, among which we remarked fresh and vigorous specimens of *Imantophyllum* minutum bearing over twenty large clusters of bright orange flowers; also good plants of the pretty white-flowered *Draconophyllum gracile*, 4 ft. in diameter. Among Everlastings, we noted a richly-coloured plant of *Phenacocma prolifera* Barneisi; also *Hederaea fuchsoides* and *H. tulipifera*. In several collections we noticed excellent plants of the scarlet-spathed *Anthurium Scherzerianum*, and also some well-flowered specimen *Heaths*, especially a plant of *Brica odora* rosea, a variety having globose, pure white, rose-scented flowers; this was in Mr. Chapman's collection, and the same exhibitor also had well-bloomed plants of *Pimelea mirabilis*, a bright rose-flowered kind, and a large well-bloomed example of *Erica ventricosa coccinea* minor. One of the best collections in the show came from Mr. Ward, whose specimens of the bluish-purple *Statico profusa*, Balfour's *Clerodendron*, *Erica ventricosa magnifica*, *Hederaea tulipifera*, and scarlet *Anthurium*, were in really excellent condition. Mr. G. Toms had a group of small but well-grown plants, consisting of an excellent and well-coloured *Hederaea tulipifera*, a floriferous example of *Erica Spenciana*, a mass of delicate rose flowers and dark foliage, also a well-flowered plant of *Stephanotis floribunda*. Mr. Wheeler showed, amongst other plants, one of *Aotus gracillima*, a graceful-habited plant, bearing racemes of handsome, orange-coloured, pea-shaped flowers. In the nurserymen's class Messrs. Jackson showed well-grown groups, as did also Mr. B. S. Williams. In these the most conspicuous plants were *Anthurium Scherzerianum*, *Statico profusa*, the scarlet and white *Clerodendron Balfourianum*, *Erica Cavendishii*, and very effective plants of *Epiparis Eolipis* and *Azalea Diana*. The finest scarlet *Anthurium* in the show, a very large-spathed variety, came from Mr. Ward. *Azaleas* were in many cases represented by fresh and floriferous plants, among which there was little novelty. *Heaths* were very attractive, the best being those sent by Messrs. T. Jackson & Sons. Among these we noted *Erica Cavendishii*, the best of all the yellow hybrids; *E. mutabilis*, with graceful, drooping, pink flowers; *E. ventricosa coccinea* minor, and *E. ventricosa magnifica*, both in capital condition; also *E. tricolor impressa*, and *E. tricolor speciosa*. Mr. Legge had a dozen well-flowered plants, the best of which were *E. Candolleana*, with salmon-tinted white flowers; *E. Victoria*, with glutinous, dark-red, white-tipped flowers; *E. ampullacea*, *E. obtata*, and *E. ventricosa magnifica*. Mr. Ward had a good group in which were *E. elegans*, *E. mirabilis*, and *E. tricolor Eppisii*, *E. mutabilis*, *E. Cavendishii*, *E. depressa*, and others. Mr. Ward had also very large and well-bloomed plants of *E. florida* and *E. profusa*, the last having glutinous dark red flowers, similar to those of *E. Victoria*. Show *Pelargoniums* in capital condition came from Mr. Ward, who obtained the first prize for nine specimens in 8-in. pots. Among these we remarked Exhibitor bright rose and black; Lady Ganning, salmon-rose, with a black spot; Warrior,

scarlet and black; *Desdemona*, white, with a maroon spot; Rob Roy, bright rose, with a maroon spot; Emperor, salmon-rose, with a maroon spot; Prince Leopold, scarlet and black, similar to Warrior; Maid of Honour, pale lilac, with a dark spot, and *Atalanta*, rose-scarlet with a black spot; other distinct kinds were Ruth, bright rose, shading into white in the centre, with a dark spot; Claribel, a pure white, with a faint rose spot; Mabel, rose-scarlet, with blotched maroon; and Countess, salmon-rose, blotched with black.

Orchids.—Among these we remarked healthy plants of *Odontoglossum vexillarium*, a species already alluded to, and *O. Phalaenopsis* and *O. Pescatorei*, all in Mr. Ward's group; the same exhibitor had also a noble plant of Stone's Lady's Slipper, bearing twenty-nine flowers, and another of the carmine-flowered *Masdevallia Harrayana*, bearing fourteen flowers. Mr. Denny had a well-grown group, the most noticeable specimens in which were *Vanda* trees, bearing twenty-rose-lilac flowers; *Cattleya Mendellii*, fresh and effective; a mass of Mrs. Benson's *Dendrobie*; a good *Odontoglossum Alexandrae*, and a well-flowered *Cattleya Mossie*. From Mr. Hepburn's garden came a well-flowered plant of *Phalaenopsis amabilis*; a good panful of the snowy-flowered *Cypripedium niveum*; a plant of the long-tailed *C. caudatum* bearing ten very fine flowers; the yellow *Anguloa Clowesii*, bearing thirteen flowers, and a strong plant of *Vanda suavis*, bearing two strong pendent flower-spikes. The same exhibitor had also a panful of the hardy North American *Cypripedium spectabile*, bearing nine fresh and lovely flowers, a well-bloomed *Dendrobium litiflorum*, and a plant of *Roezli's* *Odontoglossum*, bearing six fine flowers on two strong spikes. Mr. Philbrick contributed a collection, including a large plant of *Sobralia macrantha*, and Mr. B. S. Williams sent a fine panful of *Cypripedium barbatum*, and a well-flowered plant of *Laelia purpurata*.

Roses in Pots.—Of these some lovely groups were shown, the best being one staged by Mr. Charles Turner, in which we noted well-bloomed plants of *Princess Mary* of Cambridge, a delicate bluish variety, having soft and shell-like petals; *Madame Margottin*, a delicate sulphur Tea-scented kind; *Paul Verdier* and *Charles Lawson*, both good; *La France*, in excellent condition; also John Hopper, *Celine Forrester*, and the fiery-tinted *Edward Moore*. Messrs. Paul & Son had a beautiful group, containing plants but slightly inferior to those just alluded to. In the class for twenty specimens in 8-in. pots Mr. Turner was again first with well-grown specimens, on which were some of the finest blooms we have seen on pot plants this season. Among these were *Madame Lacharme*, *J. S. Mill*, *Etienne Lovet*, *Rev. J. B. Camm* (one of the most deliciously perfumed of all new Roses), and *Princess Beatrice*, a full pale rose variety of considerable merit. Messrs. Paul & Son were second with less compact plants, among which we noted *Centifolia rosea*, *Archie Laxton*, *Souvenir du Roi*, *Edward Moore*, and others. Messrs. W. Paul & Son showed six effective stands of out blooms; and beautiful examples of *Maréchal Niel* came from Messrs. Lane & Sons.

Miscellaneous Plants.—An effective group of Orchids, Ferns, and cut-leaved Japanese Maples, came from Messrs. Veitch & Sons, of Chelsea; among these we may mention the golden *Oncidium Marshallianum*, and its ally *O. concolor*; *Pescatorea cerina*, *P. lamellosa*, and the dark purple-flowered *Bollea Lalindei*; also a very fine specimen of *Odontoglossum navium*, *Laelia Welsholmiae*, and a large panful of the beautiful new *Boronia elatior*. Mr. Laing, of Stanstead Park, Forest Hill, furnished a tastefully-arranged collection of miscellaneous plants, among which we noted several new *Crotoms*, *Droseras*, *Caladiums*, &c. In this group was a plant of the golden-flowered *Genista prostrata* grafted on the *Laburnum* as a stock.

OBITUARY.

HENRY KINGSLEY, the novelist, and brother of the late Canon Kingsley, died during the week. He wrote pleasantly of gardening as of other matters, and was an enthusiastic advocate of hardy flowers. In an inscription in a copy of one of his books ("Geoffrey Hamlyn," now before us, he describes himself as "a fellow-soldier in the great fight against riband gardens.")

NOTES AND QUESTIONS—VARIOUS.

The Sweet Barberry (*Berberis dulcis*).—What is the name of the shrub of which I send you a specimen? Its fruit is a black berry about twice the size of a Black Currant, and similar in appearance. Is it eatable?—T. G. F. [Your plant is *Berberis dulcis*, a native of the Straits of Magellan, where the fruit is used both in a green and ripe state for Crotons pies and lards, a purpose for which it is said to be nearly as good as Gooseberries or Currants.]

Borage under Glass.—Borage becomes greatly improved in appearance when grown under glass. We usually lift some good strong plants of it in autumn, and grow them under glass, as there is frequently a demand for the flowering tops for flavouring wines, &c., when they are not obtainable from the open ground. Plants thus flowered are really quite handsome, their peculiar shade of blue being by no means common, especially in winter. Borage so readily reproduces itself from seed that, if once established, there is little fear of losing it.—J. Groom, *Henham*.

Small Plants of the White Arum (*Calla aethiopica*).—The common white greenhouse Arum (*Calla aethiopica*) is, like most other flowers, usually appreciated in proportion to its size and perfection of blossom, resulting from good cultivation; but the plant is so unique in its way that small specimens with small flowers are valued for certain purposes in decoration. Hence, we sometimes see very small plants in the market and with flowers not half the usual size. They are starved in small pots.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

A WILD GARDEN IN OXFORDSHIRE.

How much a wild garden intelligently and tastefully carried out may effect for a country seat is fairly well shown in a garden in Oxfordshire. Here our correspondent "Oxon" has formed one of the earliest, and probably one of the largest wild gardens existing, and which we, visiting it on the 27th ult., found full of novel charms. No old-fashioned garden yields its beauty so early in the year, or over a more prolonged season, than the wild garden, as there is abundant evidence here, but our impressions shall be those of the day only. Thus, writing at the end of May, we may serve to throw light on the possibilities of garden embellishment in one way at a season when there is a great blank in many gardens—the time of "bedding out." "Oxon" had no favourable or inviting site with which to deal; no great variety of surface, which makes attempts in this direction so much easier and happier; no variety of soil, which might enable plants of widely different natural habitats to be grown; only a neglected plantation, with rather a poor gravelly soil and a gentle slope in one part, and little variety of surface beyond a few gravel banks thrown up long before. The garden is, for the most part, arranged on each side of a Grass drive among rather open ground, between trees on the one hand and rather shady ground on the other. The most beautiful aspect at the end of May of this singularly ungenial spring, which has not allowed the Peonies to unfold here yet, is that of the German Irises, with their great Orchid-like blossoms seen everywhere through the wood, clear above the Grass and other herbage, stately and noble flowers that, like the Daffodils, fear no weather, yet with rich and delicate hues that could not be surpassed by tropical birds or flowers. If this wild garden only teach this effective way of using the various beautiful and vigorous kinds of Iris now included in our garden flora it would do good service. The Irises are perfectly at home in the wood and among the Grass and wild flowers; we have never before seen them to such advantage. By-and-by, when they go out of flower, they will not be in the way as in a "mixed border," tempting one to remove them, but grow and rest quietly among the Grass until the varied blossoms of another year well repay the trouble of substituting these noble hardy flowers for some of the familiar weeds and wild plants that inhabit our plantations. In the wild garden the fairest of our own wild flowers may be happily associated with their relatives from other countries. Here the sturdy Bell-flowered Scilla (*S. campanulata*) grows wild with our own Bluebell (*S. nutans*); the white and pink forms also of the last-named look beautiful here associated with the common well-known form. The earlier Scillas are of course past; they are admirably suited for the wild garden, especially *S. bifolia*, which thrives freely in woods. The Lily of the Valley did not inhabit the wood before; therefore it was pleasant to thin out some of its over-matted tufts and carry them to the wild garden, where they are now in fullest beauty. It is associated with its tall and stately relation the Solomon's Seal, which we never saw to such perfection as in this wild garden, the partial shade suiting it. The Solomon's Seal, which is usually effective when issuing forth from fringes of shrubberies, is here best arching high over the Woodruff and other sweet woodland flowers, among which it seems a giant, with every leaf, and stem, and blossom full of lines of beauty. The additional vigour and beauty shown by this plant when in rich soil well repays one for selecting suitable spots for it. The greater Celandine (*Chelidonium majus*) and its double form are very pretty here with their tufts of golden flowers; they grow freely and take all needful care of themselves. The same may be said of the Honesty, the common forms of Columbine, and Allium Moly, an old-fashioned plant, and one of the many subjects at home in the wild garden, and which are better left out of the garden properly so

called. Of past and future effects we said we would say nothing, but the myriads of Crocus leaves dying off without the indignity of being tied into bundles as is common in gardens, the dense growth of Aconite and Snowdrop leaves, of coloured and common Primroses and Cowslips suggest the beauty of this wild garden during the past spring. The yet unfolded buds on the many tufts and groups of the numerous herbaceous Peonies promise noble effects early in June; so do the tufts of the splendid Eastern Poppy (*Papaver orientale*) and the Lilies, and Sweet Williams, and Adam's Needles, and many other subjects, that will show their blossoms above or among the summer Grass in due time. One of the most beautiful and free-growing orders of plants among those most suitable for the wild garden is the Borage or Forget-me-not Order; among the best of these here at present are the Caucasian Comfrey (*Symphytum caucasicum*) an admirable wood or copse plant, and red-purple or Bohemian Comfrey (*S. bohemicum*), which is very handsome here. And what lovely effects from the Forget-me-nots—the wood Forget-me-not, and the Early Forget-me-not (*M. dissitiflora*) are here! where their soft little clouds of blue in the Grass are much prettier than tufts of the same kind surrounded by the brown earth in a prim border. Here the pushing of the delicate Grass blades through the blue mass and the indefinite way in which the fringes of the tufts mingle with the surrounding vegetation are very beautiful. The only noticeable variation of surface is that of some gravel banks, which are properly covered with Stonecrops, Saxifrages, and the like, which would, as a rule, have a poor chance in the Grass. Surfaces that naturally support a very sparse and dwarf vegetation are valuable in a garden as they permit of the culture of a series of free-growing Alpine and rock plants that would not be able to hold their own among Grass and ordinary weeds and wild flowers. One of the happiest features of this wild garden results from the way in which dead trees have been adorned. Once dead some of the smaller branches are lopped off, and one or more climbers planted at the base of the tree. Here a Clematis, a climbing Rose, a new kind of Ivy, a wild Vine, or a Virginian Creeper, have all they require, a firm support on which they may arrange themselves after their own natural habit without being mutilated or without trouble to the planter, and fresh ground free to themselves. In this way the more vigorous of the new Clematises may be grown to perfection. What an admirable way, too, of growing the many and varied species of Clematis! to our thinking as beautiful as those with flowers as large as saucers. Even when an old tree falls and tosses up a mass of soil and roots the wild gardener is ready with some subject from his mixed border to adorn the projection, and he may allow some choice Bramble or wild Vine to scramble over the prostrate stem. A collection of Ivies grown on old tree-stems would be much more satisfactory than on a wall, and not liable to rob each other at the roots and interfere with each other in the air. Ferns are at home in the wild garden; all the strong hardy kinds may be grown in it and look better in it among the flowers than in the "hardy Fernery" properly so called. Even more graceful than the Ferns, and in some cases more useful because they send up their plume-like leaves very early in the year, are the giant Fennels (*Ferula*), which grow well here and hold their own easily among the strongest plants. The common Fennel is also here, but it seeds so freely that it becomes a troublesome weed and shows a tendency to overrun plants of greater value. This reminds us of certain subjects that should be introduced with caution into all but the remotest parts of the wild garden. Such plants as *Heraclium*, Willow Herb, and many others that overcome all obstacles, and not only win but destroy all their fellows in the struggle for life, should only be planted in outlying positions, islands, hedges, small bits of isolated wood or copse, where their effects might be visible for a season, and where they might ramble without destroying. In short, they never should be planted where it is desired to encourage a variety of beautiful subjects. Rabbits—dreaded vermin to the wild gardener—are kept out here effectually by means of wire fencing. The presence of these pests prevents all success in the wild garden. It would be well if one could keep out slugs by the same simple means. The encouragement of creatures

that feed on slugs is desirable, as these are the most potent cause of mischief to hardy flowers. To succeed with the wild garden, one should have a good collection of hardy flowers from which it can be supplied. "Oxon" has formed an excellent one, consisting of about 1100 species mostly arranged in borders. From these, from time to time, over-vigorous and over-abundant kinds may be taken to the wilderness. In a large collection one frequently finds species most suited for full liberty in woods. The many subjects good in all positions, may increase in these borders till plentiful enough for planting out in some quantity in the wild garden. The wild garden to which we have been adverting has been wholly formed by Oxon," who planted with his own hands the various subjects that now adorn it throughout the year. It has been done within four or five years, and, therefore, many of the climbers have not as yet attained full growth. We need hardly point out how agreeable the work, or what a charming source of exercise and amusement it must be to a lover of flowers, even apart from the rich harvest of beauty, one phase of which we have tried to describe.

W. R.

[We shall be grateful to any of our readers who may send us information as to other successful experiments in the formation of wild gardens. The movement is a healthy one, and likely to add much to the interest of country gardens and country life, and accounts of successful beginnings in this way would probably be of service to many of our readers.]

VEGETATION OF CORSICA.

THREE separate upheavals have occurred in the formation of Corsica. The first and remotest brought up from the floor of the Mediterranean a long chain of granite, that extended from Cap Corso in the north of the island to the Straits of Bonifacio in the south; this bare range may, therefore, be regarded as the backbone of Corsica. After a long lapse of ages a second convulsion gave us another upheaval of granite, with its attendant conglomerates of porphyry and serpentine coalescing or overlying, as the case might be, and giving breadth and compactness to the earlier granite chain. Again another lapse of time, and a third upheaval deposited, more especially in the north and south, layers of carboniferous and allied limestone, that formed a sort of breastwork or shoulderwork to the granite, thus mellowing and fertilising the naked mass. Time has brought down to the valleys or sea-coast line a *débris* formed from the gradual wearing down of these upper rocks, and the result has been a rich and varied soil that is clothed with a corresponding vegetation. We may divide the botany of Corsica into three zones, and I would remark that these zones or belts largely partake of the vegetation of those countries that they severally face, France, Spain, Barbary, and the Italian mainland being each represented. The tract approaching the shore gives us the first zone. This is the *Mâquis* (*Macchia*-bush or scrub) of the island. It consists principally of evergreen shrubs thickly massed and matted together. I counted no fewer than forty of these shrubs and creepers, which often attain large dimensions. The more conspicuous among them are the *Arbutus Unedo* with Strawberry-like fruits, the broad and narrow-leaved *Myrtles* in rich black berry, the *Cistuses* (C. *monspeliensis*, *salsifolius*, and *corsicus*), the fruiting *Lentisk tree* (*Pistacia Lentiscus*), *Lavender* (*Lavandula Stoechas*), the *Phillyreas*, the *Indian Fig* in flower and fruit, the *Rosemary*, *Tree Heath* (*Erica arborea*), *Rhamnus Alaternus*, *Laurustinus*, *Smilax aspera*, and notably *Haliclysum angustifolium*, which the *Rancus aculeatus* loaded with coral berries, *Inula viscosa*, the *Madder* and *Asphodel*, the prickly *Corsican Broom* (*Genista corsica*), the *Daphne* (*D. Gnidium*), and the *Clematis* (*C. Vitalba* and *Platanula*). Here and there, where the bush has been cleared vineyards and Orange and Lemon groves are found together with tracts of cereals, that seem to thrive with but little trouble on the part of the cultivator. The second zone embraces plantations of Olive trees, trenched and terraced as we find them in the Riviera; here, too, are the Chestnut, Fig, and Almond, which ripen their fruits in perfection; the Chestnut, indeed, flourishes at an altitude of 5000 feet. The third zone, and the highest, adapts itself to the growth of forest trees. Here flourish the *Pines* (*Pinus Laricio* and *Picea*), the *Ilex* and *Yew* among evergreens, the *Beech* and *Alders* (*Alnus inaequalis* and *cordata*), and *Larch* and *Oaks* among deciduous trees. Corsica abounds in *Liliates*. These, indeed, cover every portion of the land, and perfume the air to such an extent that Napoleon, when an exile in St. Helena, was heard to say that he could tell his native Corsica, even though his eyes were shut, by the aroma that was shed around by the vegetation.

Hovingham Lodge, York.

PETER INCHBALD.

ADVANTAGE OF SUMMER MULCHINGS.

DURING very dry weather, after the ground has been previously warmed by means of sun-heat, mulching is highly beneficial, not only in the vegetable department, but also in that devoted to fruits and flowers. It saves much labour in watering, and also helps to enrich the soil. If we mulch a Vine border in autumn with litter, leaves, or half-rotten manure, these materials will, to some extent, retain the heat absorbed during summer, and will help to keep the roots warm; but if the mulching be left on during the warm days of spring and the early part of summer it will prevent the roots being benefited by the heat derived from the increased sunshine. It is clear, therefore, that both in the case of vegetables and that of flower-beds it is necessary that the soil should be warmed to some extent before mulching is applied, as after that not only is moisture longer retained in the ground, but the latter is kept proportionately cooler than it otherwise would have been. Mulchings are disliked by some on account of their untidy appearance, especially when scattered about by birds in search of food in dry weather; but their benefit to vegetation in hot weather is indisputable. The best material for mulching is partly decayed hot-bed manure, but when this cannot be obtained, short Grass from the lawn may be used with advantage. All fruit and vegetable crops, as has already been stated, are benefited by being mulched, but some of them more so than others. The Raspberry, which delights in a moist soil, with its roots near the surface, should always be mulched in dry situations. Even on soils that are thin and otherwise unsuitable for Raspberries, good crops of that fruit have been obtained by mulching. Pyramidal and bush fruit trees that are occasionally root-pruned should also be mulched, especially in dry seasons, with half-rotten manure; but the mulching should not be applied too early, as in that case it prevents the sun from warming the soil left cold after the winter. Its good effects on the growth of young Gooseberries and Currants, and on that of stone fruits, are very conspicuous; all newly planted trees, too, are the better for being mulched both winter and summer. As regards Strawberries, the crop is quite doubled in bulk when the plants are properly and carefully mulched as they come into bloom. Celery, too, when mulched with short Grass, requires but little water, and its growth is more robust and succulent than when otherwise treated. In dry summers, and more especially towards autumn, Peas often become affected with mildew, unless a good mulching of manure about a foot wide be laid along the sides of the rows—a mode of treatment which greatly improves the crop. Winter Greens and autumn Cauliflowers progress slowly when planted in dry hot weather in June, but if the ground be but even sprinkled over with short Grass, they will be found to grow away freely. Potatoes are an exception; they do best without mulching; for should the autumn prove wet, it would certainly aggravate the disease. In flower gardens mulching is highly beneficial, but it is unsightly if not covered with mould. In the case of Calceolarias, it is absolutely essential, in order to maintain healthy vigour and keep off disease. *Iresnes*, which are moisture-loving plants, when well mulched thrive and prosper in situations in which they would otherwise scarcely exist. Roses, too, should be mulched with horse manure, the fertilising properties of which get washed down by means of rain and artificial waterings to the root. The best mulching for flower gardens is Cocoa-nut refuse; but where the beds are large it would be too expensive, and in that case half-decayed vegetable mould, or half-rotten manure put through an incline, would probably answer the purpose, and not be unsightly. Plums, Peaches, Figs, or Vines grown in large pots should be mulched two or three times during the growing season, inasmuch as the roots are generally near the surface and are liable to suffer from want of water. Setting aside the advantages of mulching, as regards the saving of labour and retaining moisture in the soil, it keeps the roots in an even temperature and prevents the escape of heat from the ground in cold weather.

R.

'Haricot Beans.—There is seldom much difficulty in getting a fair variety of vegetables throughout the summer months, but in winter it is not so easy. As one means of providing it at a cheap rate, we would recommend the growth of *Haricots*. They are very productive, and a few rows will provide a continual supply of these nutritious vegetables. The tall varieties might often be grown on vacant walls or fences, or be allowed to ramble over the roofs of outhouses, clothing these with verdure, while contributing to the supply of the table. There are several varieties; but the Dwarf White Runner and Dwarf White Haricot are perhaps as good or better than any other. There is also a very large white variety which grows to a great height, and is large in pod and bean, and very prolific. The culture of *Haricots* is identical with that of the common French and Runner Beans. The soil can hardly be too rich for them if perfection be aimed at. A deep till, abundance of manure, and a warm, rather dry site are conditions most favourable to this crop.—D. T. FISH.

HOW TO DRY PLANTS.

The materials recommended for this purpose by the Rev. George Henslow, in a contemporary, are common cartridge-paper, thick white blotting paper, cotton wadding, and millboard, all cut to the same size. The plants should be gathered in dry weather, and soon after the flowers open, when their colours are brightest. Succulent plants (such as *Daffodils*, *Orchises*, or *Stoncrop*s) should be put into scalding water, with the exception of the flowers, for a minute or two, then laid on a cloth to dry. Arrange the specimens and papers in the following order:—Millboard, cartridge-paper, wadding (split open, and the glazed side laid next to the cartridge-paper), blotting-paper; the specimens having small pieces of wadding placed within and around the flowers, to draw off all the moisture as quickly as possible, blotting-paper, wadding as before, cartridge-paper, millboard. When the specimens, &c., are thus arranged, heavy weights should be put on them: about 30 lbs. the first day, 60 lbs. afterwards. Remove them from under pressure in a day or two; carefully take away all the papers, &c., except the blotting-papers between which the specimens are placed; put these in a warm air to dry, whilst the removed papers, &c., are dried in the sun or by the fire. When dry (but not warm) place them in the same order as before; put all under the heavier pressure for a few days, when (if not succulent) they will be dry. Flowers of different colours require different treatment to preserve their colours. Blue flowers must be dried with heat, either under a case of hot sand before a fire, with a hot iron, or in a cool oven. Red flowers are injured by heat; they require to be washed with muriatic acid, diluted in spirits of wine, to fix the colour. One part of acid to three parts of spirit is about the proportion. The best brush with which to apply this mixture is the head of a Thistle when in seed, as the acid destroys a hair pencil, and injures wherever it touches, except class or china; therefore it should be used with great care. Many yellow flowers turn green even after they have remained yellow some weeks; they must, therefore, be dried repeatedly before the fire, and again after they are mounted on paper, and kept in a dry place. Purple flowers require as much care, or they soon turn a light brown. White flowers will turn brown if handled or bruised before they are dried. Daisies, Pansies, and some other flowers must not be removed from under pressure for two or three days, or the petals will curl up. As all dried plants (Ferns excepted) are liable to be infested by minute insects, a small quantity of the poison, corrosive sublimate, dissolved in spirits of wine, should be added to the paste, which it will also preserve from mould. The best cement for fixing the specimens on to the paper or card-board is gum paste. It is composed of thick gum-water and flour mixed in warm water, by adding the two together warm, and of a consistency that will run off the hair brush.

Diseased Phloxes.—Being an old grower of Phloxes, and the possessor of a fine collection of them, I think I can throw out a suggestion that will meet the difficulty in which "Rose" (see p. 498) is placed. My Phloxes have been affected with the same complaint as hers, and my remedy, which is as follows, has always proved effectual. When checked in the manner she describes, the best plan is to cut them hard in, say to one or two eyes, and re-pot them, giving them a liberal shift and just sufficient water to keep the soil moist; this will eradicate the evil without fail. In answer to the query as to whether Phloxes are more delicate now than formerly, my experience induces me to form an opposite opinion. Some of the newer high-coloured varieties may be a little delicate, but, take Phloxes as a whole, they possess more vigour, and are certainly better in habit, than the kinds which we used to grow years ago.—F. T. DAVIS, Plumstead Common.

Ornamental Hedges.—In reply to "Ellerslie's" inquiries (see p. 510) with regard to the Wild Rose, as recommended recently for hedges, together with the Wild Clematis, or Travellers' Joy, I can state with confidence that I believe the Wild Rose to be quite as capable of being kept within any desired bounds as to height or thickness as any other Rose, but the principal advantage of its employment in hedges is the combination of great strength and powers of resistance, by means of the length of the sprays which can be entwined like basket-work, or, if the locality permit, hung in garlands from bush to bush (if such be planted) in the hedge. There is no difficulty in making an ornamental flowering hedge within the boundary of a garden, against lattice-work or wires, but the hedge for which Wild Roses were recommended was intended as an impassable barrier, to combine ornament with use; and were I again to make a new hedge, I should facilitate the process by straining strong tarred cord through any common posts, for the purpose of interlacing in the firmest manner the thorny shoots of the Wild Rose as they grew, by which means, long before the tarred cord would have rotted away,

the hedge would be self-supporting by means of a sort of natural basket-work, similar to that which I have seen in Germany, in the case of Quicks. When the latter are planted on each side of small sticks, crossed diamond-fashion (like those placed for the support of Kidney Beans), the shoots become entwined with each other and interlaced with the sticks. In course of time the sticks rot away, but the fence is so close, strong, and firm, owing to the growth of the boughs thus trained, that it would be almost impossible for a cat to pass through it, even at the bottom. The Quick is, however, a slow-growing and expensive fence, and one which requires a good deal of culture as regards the soil in which it is planted, and a great deal of attention afterwards, and there is no doubt that our native thorny climbers, the Wild Rose, Bramble, &c., might be substituted for it with advantage, both as regards utility and expense, and they would be more ornamental.—L.

— We have an ornamental hedge here which would probably suit your correspondent (see p. 510). A piece of rabbit-netting of the height desired is stretched along the line where the fence is required, and fastened to posts made either of iron or wood. The ground is then thoroughly trenched, adding at the same time plenty of manure. Ivy is then planted thickly and tied to the netting, and at every 5 or 6 ft. apart a Honeysuckle and the old pink and crimson China Roses are planted, but no Clematises, as these would have but little chance with the Ivy. The effect of the hedge when the Honeysuckle and Roses are in bloom is charming, and the Roses keep blooming generally up till Christmas.—J. B.

Climbers on Dead Trees—Ornamental Gourds.—The readers of THE GARDEN are much indebted to a recent correspondent for this excellent plan of rendering dead trees ornamental, and a further benefit would be conferred by the names of an additional number of annuals which would reach the desired height in the course of the season; and still more valuable would be a list of the quick-growing wild or cultivated Roses and other perennials, which would flourish and grow quickly under shade when planted against forest trees. With regard to annuals, one of the most striking garden ornaments on the Continent (even in the northern parts of Italy, and also portions of Switzerland), are the Pumpkins, which are planted at the foot of large trees, grow to a considerable height, twine along the branches, and bear fruit in abundance; but such ornaments are never seen in any part of Great Britain, and though Pumpkins and Gourds are grown to some extent (though too sparingly) in our gardens, yet the edible kinds are never seen climbing up trees, and numberless beautiful ornamental miniature varieties in the form of Pears and Oranges, in every shade of green and yellow, besides pure white, with their very fine foliage, are scarcely ever trained as they ought to be among flowering plants, so as to render hedges more effective, or against wire or wooden trellises: thus managed, they have a beautiful effect, and cannot be too highly recommended.—L.

Tree Pictures in Kensington Gardens.—The crowds who flock to Bushy Park or Kew do not see, says the "Times," anything more fair than the tree pictures now in Kensington Gardens. The Hawthorns and Horse Chestnuts are now in marvellous beauty, though one rarely sees anybody taking the least notice of them. All the blaze of the autumnal bedding out is in point of beauty as nothing compared with what is now afforded here by a few kinds of ordinary hardy trees that cost little at first and take care of themselves afterwards. There is a little open lawn with a small Lime tree in its centre quite near the Row corner of the Gardens, around which there are several charming aspects of tree beauty. One Hawthorn is about 40 ft. high. Some of the central and unfrequented portions of the Gardens are the most attractive. Nobody can despair of growing flowering trees to his heart's content in London after seeing the mountains of Horse Chestnut bloom and other masses of tree flowers here. Let those interested see the old trees in the central parts as well as the newer plantations, which, however, are also beautiful.

Converting Carboys into Hand-lights.—To cut glass vessels neatly, heat a rod of iron to redness, and having filled the vessel the exact height you wish it to be cut with oil of any kind, proceed very gradually to dip the red-hot iron into the oil, which, heating all along the surface, the glass suddenly chips and cracks right round, when you can lift off the upper portion clean by the surface of the oil. The bottoms of carboys and bottles, according to the "Gardeners' Magazine," can be cut off by making a slight nick with a file and then marking round with a streak of water where you want it to come off. Make an iron red-hot and lay it on the nick. This will cause it to expand and crack, then by moving the rod round the crack will follow. When the carboys are rather large, it is better to have two rods heated, or while you are reheating the iron, the crack might take a transverse direction.

NOTES OF THE WEEK.

— THE Royal Botanic Society have completed their fine conservatory in the Regent's Park by the addition of another wing. It is built by Mr. Turner, of Dublin, whose curvilinear iron glass-houses are among the best we have seen. We hope the Society may some day possess a collection of well-grown plants in this house, which is now perhaps the finest large house for growing plants in the neighbourhood of London.

— AMONG the old flowers that bloom at this season is the common Greek Valerian (*Polemonium coruleum*): a large flowered form, called *P. œruleum grandiflorum*, now in bloom is sufficiently distinct to merit general culture as a border flower. We believe it is in Messrs. Henderson's collection, and we noticed it among the border flowers at Crowley Park.

— THERE are some who admire single Roses, some, too, single Camellias, and in each case with good reason, we think. Single Peonies have, probably, fewer admirers, and yet one (*P. Whiteleyi*) sent to the Aquarium Exhibition by Mr. Parker, of Tooting, is one of the most beautiful flowers we have ever seen—a large white bloom, with a huge boss of yellow stamens in the centre.

— WE saw the other day at Messrs. Hooper's, in Covent Garden, a compact-habited, double-flowered *Begonia*, named *B. salmonea fl.-pl.*, which differs from all others that we have yet seen, in bearing only male flowers. These are produced in clusters of from two to five on a scape from 6 in. to 9 in. in length, and are of a delicate rosy-salmon colour. It promises to be a useful plant for decorative purposes.

— MR. ROBERT OSBORN sends us specimens of *Camaejas* now in flower in his Nursery at Fulham. "The first flowering one (*C. esculenta*) has been for some time in great beauty, but is beginning to fade; *C. tardiflora*, a kind which seems to be very little known, is, however, now coming on to replace it; both are among the most plentiful of our spring flowers. The colour is a lovely blue, and in a mass, as we have them, the effect at a distance as well as close is very beautiful."

— *IBERIS CORREIFOLIA*, now in bloom in many gardens, seems to possess the (to many) valuable qualities of thriving perfectly in the polluted air of cities. In Victoria Park there are thousands of snowy masses of this plant, though the air there of late years has been most destructive even to many trees and shrubs usually supposed to withstand the evil effects of smoky, dusty, and otherwise polluted air.

— THE variegated form of the now popular *Spiræa* (*Hoteia*) *japonica* is valuable for its flowering qualities apart from the variegation. The flower-stem is dwarfer, and the panicle more compact than is the case with the ordinary green-leaved form. Mr. R. Parker, who grows both forms admirably in pots, pointed out this peculiarity to us the other day, and the fact is worth noting by those who grow herbaceous plants in pots for exhibition or other purposes.

— OUR London flower shows are now a-days so deficient in surprises, so far as the larger class of specimen plants are concerned, that it was somewhat of a relief to find Messrs. Lucombe & Pince sending superbly grown collections of plants all the way from their famous nursery at Exeter, and besting some of our most successful exhibitors. We are informed that a specimen of *Ixora javanica*, in the Lucombe Nursery, now coming into flower, promises to bear 200 trusses.

— MR. CULLEY, writing to us on the 29th ult., says that *Dendrobium Falcooneri* is in great beauty at Ferniehurst, and that when all the flowers shall have opened they will amount to eighty-three. The flowers measure $\frac{4}{5}$ in. across, the lip itself being $1\frac{1}{2}$ in. broad. On six growths of *Dendrobium Devonianum* there are 189 flowers; and *Utricularia montana* is producing 136 spikes, each bearing from four to seven flowers. On eleven spikes of *Odontoglossum vexillarium* there are fifty-two blooms, which in the course of a week will be in great beauty, the kind being the bright pink variety. On *Odontoglossum B. nudi* we had last month sixty spikes of flowers, and have now as many as forty, all in great beauty. *Odontoglossum Pescatorei* has six spikes and twenty-five flowers on the spike; and *Odontoglossum nævium* and *O. Roezlii* are nearly equally good.

— WE see so much of the West End parks and their beauties that the various charms of Victoria Park are perhaps taken less notice of than they deserve. It is, however, very beautiful at this season, now that the various flowering trees and shrubs are in blossom. The islands are particularly noticeable, showing, as they do, a fine variety of tree forms, relieved here and there by flowering shrubs. Beneath the trees and shrubs is a carpet of the common Red Lychnis, which covers the banks, and comes down to the edge of the water, forming rosy meadows of flowers. The design

in various parts being natural and graceful, there are many pretty peeps to be seen. Later on the fine display of bedding plants now being prepared by Mr. McIntyre will be very attractive.

— DAFFODILS are planted on Grassy banks in Victoria Park, where they bloom and go to rest before there is any need for much mowing. If this may be done in the more central parts of a pleasure garden, as in this case, how much more conveniently may the system be carried out in less prominent positions.

— THE "Floral Magazine" is henceforward to be edited and its plates drawn by Mr. F. W. Burbidge, and the number just issued contains four plates drawn by him. They consist of *Phalœnopsis Veitchii*, *Hibiscus Coleridgei*, *Auricula Alexander Meiklejohn*, and hybrid perpetual Rose, Duke of Connaught, one of the finest of the new Roses.

— SOME of our readers may remember that an unprincipled contractor undertook to improve Euston Square—and how he converted it into a rubbish shoot. The "Gardeners' Chronicle," in printing a paragraph commenting on this, adds the following editorial note:—"The gardens on the Thames Embankment and in Leicester Square are also not creditable to those who have the management." It is with reluctance we comment adversely on any course taken by a contemporary journal, but in this case it is only justice to the superintendents of the gardens mentioned to say that they are in as good condition as any other public gardens about London, and that there is no reason whatever for associating the Thames Embankment gardens with the rubbish shoot in Euston-square.

— THE Japan Lady's Slipper (*Cypripedium japonicum*), a rare and curious hardy Orchid, is now in flower in Messrs. Rollisson's Nursery at Tooting, and we recently saw some strong growths of it in Mr. Ware's Nursery at Tottenham, where the plant has stood out all the winter in an open-air bed. This Lady's Slipper is one of the most singular in the whole group to which it belongs, the fresh green leaves being borne in pairs like those of the common Tway-blade (*Listera ovata*), only in this case they are in shape like a lady's fan, the outer margin being irregularly torn or jagged; the sepals and petals are greenish suffused with brown, and the lip is rosy-purple veined with a deeper purple. It is satisfactory to find this Lady's Slipper so hardy and amenable to culture, inasmuch as it is one of the most interesting and precious of all plants for planting along the outer margins of sheltered bog gardens associated with *C. spectabile*, the golden-lipped *C. pubescens*, and the purple *Sarracenia* or Huntsman's Cup.

Variegated Abutilons.—Among these the somewhat common *A. Thompsoni* is still one of the best for either indoor or outdoor decoration, but it is in a cool, airy, light greenhouse that it is seen to perfection, as its ornamental and prettily-variegated foliage is under such circumstances fully developed. Grown in a hot, moist stove, it is a poor weedy plant, with almost green leaves; but in a cool house the bright mottling of the foliage is very distinct. The slender and erect habit of the plant necessitates its culture in small pots, and frequent stopping, so as to have plants about 6 in. or 1 ft. in height, furnished with leaves to the bottom. For side plants for table decoration these small Abutilons are admirably adapted, and the variegation is of a striking kind under artificial light. Still neater in habit, and more profusely and constantly variegated, is the narrow, angular-leaved *A. vexillarium*, which also grows slower and retains its leaves better. It is an excellent edging plant for large vases, and associates well with Maiden-hair and other Ferns in such positions. Cuttings made of the tops strike readily, and if a slender stake is put to the shoot—for it keeps to one shoot as a rule—it forms one of the neatest little plants that could be desired, and a quantity of it sprinkled throughout the greenhouse gives quite a lively aspect at any season, for it can be had all the year round. I keep all my plants in 3-in. pots chiefly in order that they may fit into small vases; but it, and indeed the other kinds as well, belongs to that class of plants which will bear turning out of their pots for a few days when required, without much injury. One of the most striking of the species, however, is *A. marmoratum*, which makes a capital table plant. The leaves are broad, measuring nearly 6 in. across, distinctly heart-shaped, and present different shades of variegation, varying from pale yellow to bright green—the yellow tints predominating. The plant is symmetrical in shape, too, and on the whole is one which will commend itself to cultivators, as being generally useful. I have at present a number of useful plants of it in 4-in. pots, which have been frequently in and out of the house without showing any bad effects. Among other ornamental-leaved Abutilons may be mentioned *A. tessellatum* and *A. variegatum*. They all strike easily from cuttings, and thrive in a compost of loam, leaf-mould, and sand.

—CHEF.

THE FLOWER GARDEN.

PREPARING AND PLANTING FLOWER-BEDS.

NEXT to the propagation of the plants, the work of preparing beds for them is the most important. Irreparable mischief may be, and often is, done at this stage, and more particularly when the furnishing and planting of the garden is done by contract, as is now frequently the case with villa gardens in the neighbourhood of towns. Manure must be given either when the beds are dug before planting, or in autumn. Most bedding plants are gross feeders, and, being generally planted thickly, they soon impoverish the soil. Besides, rotation cannot often be practised in the flower garden, and the same species have usually to occupy the same beds year after year. Liberal manuring is therefore essential, and no one will neglect it who desires to see his beds well filled during the summer months; and it may just be hinted that the fewer the plants, the higher should be the culture. But thick planting should be the rule, for in this country we are compelled to delay bedding out till so late in the season, that we cannot afterwards wait till the plants grow. Rank manure is not objectionable if it be dug

into the beds in autumn, but it should be well rotted if given in summer. Let me now advert to the digging of the beds, an operation which is seldom done well by an ordinary workman if left to himself. He does not go into the corners of intricate figures; and digging closely but carefully up to the Box or Grass edgings, so as to leave a good deep tilth for marginal plants instead of a hard crust, is too much for his patience. I always feel all the corners and edges with a stake before commencing to plant, in order to make sure that they have received attention. The digger should begin by first "nick-

ing off" his edges and cleaning all the weeds, &c., therefrom; and in digging he should have a good opening, that he may see what he is about—take thin spits, which should be thoroughly broken up as they are turned over, disintegrating the manure also, and mixing it with the soil as he proceeds—and when coming to the edge of the bed, or to a point, he should cut straight down close to the edging, and then turn the spit over its full depth. If he be a good workman, he will preserve the outlines and contour of the bed as he goes on; but any unevenness can be rectified at the end by a few touches of the spade, and the bed is ready for the plants. No raking is admissible in a flower-bed; the spade, the trowel, or the hand can do all that is wanted. As to planting, all good cultivators follow the digger, for the ground is always in best condition, either for planting or sowing, when it is newly turned over. Assuming that the arrangements as to colours have been made previously, the plants should be brought and placed beside the beds which they are to occupy, and the night before they are put out, or at least a few hours previously, they should be well watered, for it is an evil practice to plant them in a dry state. At the same time the roots should not be in a saturated condition, especially in the case of such plants as Alyssums, Lobelias, Verbenas, &c., which are generally pro-

pagated in boxes. If they be wet, the roots cannot be disentangled without injury; but when the soil about them is moderately dry, they shake out freely without injury. With pot-bound plants, it is enough usually to remove the crocks, liberate the bottom roots, and to break down the top edges of the ball a little, and plant, filling in the soil loosely, and pressing it with the hands at the neck of the plant to steady it; but all ramming should be avoided. Plants never take kindly to a bed that is tapped or beaten, and in the case of Calceolarias such a condition is simply ruin. In planting the latter, and indeed all boxed or prickled-out plants get them up first with good balls, keep the roots shaded from the sun and protected from the dry air, and plant them expeditiously but with care, making the holes large enough for the balls, that there may be no necessity for squeezing them down, which is often done by careless and inexperienced planters. Little harm accrues from burying a few of the bottom leaves of a Verbena or Calceolaria; for it insures their roots being well covered, and it is therefore better to err on the side of deep planting than otherwise. Many failures happen through the shallow planting of tender subjects. I plant thousands of Alyssums, Lobelias, and similar plants every

year, just out of the cutting pots, without any soil whatever to their roots; but I do not simply scratch a hollow on the surface of the bed and place the roots in it, where they will be disturbed every time the bed is stirred, and roasted by the sun in dry weather. On the contrary, their feeding points are placed within reach of moisture at once, and out of danger from hoe-stirring. A deep slit is made in the soil with the trowel, and holding the soil back with the other hand, the operator drops the long roots into the hole perpendicularly, and, withdrawing the trowel, allows the soil to fall into its place again. In

Rubus deliciosus.

this way the most tender subjects, and those which usually do not succeed well when moved, may be transplanted successfully. It is only necessary to sow them in fine soil that will shake freely from the roots without damaging them, and to take care to drop them straight down into the holes in planting. Unless it is raining at the time, all newly put-out bedding plants should be watered as soon as planted, and watered copiously; and the day following, or as soon after as possible, the surface of the beds should be stirred with the hoe, or, in the case of shallow-planted subjects, with the hand. This prevents evaporation, and is next to mulching in that respect, and should never be neglected after artificial waterings, which have a tendency to make the surface of the soil cake and crack in dry weather.

CHIEF.

A SHOWY WHITE-FLOWERED BRAMBLE.

(*RUBUS DELICIOSUS.*)

THOUGH rarely seen in gardens, this is one of the most striking of all early-flowering shrubs; it was originally discovered in 1822 by Dr. James, who found it on the Rocky Mountains, where it grows at considerable elevations. The plant was brought into cultivation in this country by Mr. Anderson-Henry, of Hay Lodge, Edinburgh, who

raised it from North American seeds, the produce of which first bloomed in May, 1870. Our illustration was prepared from a bush of it 4 ft. high, in the Royal Botanic Gardens, Regent's Park, where we saw it in May last, bearing numerous large white flowers among serrated trilobate leaves. Its single Rose-like blossoms are succeeded by reddish-purple Blackberry-looking fruits, which have an agreeable flavour. The plant is perfectly hardy, and is well worth a place in every choice collection of flowering shrubs; its proper position, however, is unquestionably on the outskirts of plantations or in the wild garden. Like nearly all other species of *Rubus* it may be readily increased by means of root-cuttings. B.

Street Gardening.—Passing the other day through a crowded street at Boston, in Lincolnshire, I was agreeably surprised by observing what may be accomplished in street gardening. In front of a small house was a spot of greenery most pleasing to the eye; the size, about 24 ft. by 12 ft. A border, only about a yard wide, extended round the whole, edged with black tiles, over which curled a large-leaved marbled Golden Ivy. The centre of the ground was covered with ordinary red gravel. Close to the street railings was a long bed of Lilies of the Valley full of bloom, shedding their delicious odour for the benefit of passers-by. There were also shrubs, such as Berberis, Golden Holly, Golden Euonymus, and Cupressus, ferns being underneath the windows. Within the edge of Ivy were *Gentianella* and *Iberis sempervirens*, clumps of *Hepatica*, *Anemone penina*, and *Muscari* (the flowering, of course, over). In the corners were fine plants of *Arum Draconculas*, and clumps of the graceful-habited *Solomon's Seal*, as green and fresh as if in the depths of a wood. There were also plants of *Anemone japonica alba*, *Ranunculus acontifolius* (Fair Maids of France), *Dielytra*, and the pale blue *Camassia* and *Scarlet Lychnis* coming into flower. The border had also evidently been thickly studded with Tulips and Hyacinths. Nothing, however, looked crowded. I had almost forgotten to say that a small golden-edged Ivy climbed up the brick front, and the whole was shaded by two Lime trees growing in the central gravel plot. The effect in a dry, dusty street was unique.—D. H.

Cottage Gardens v. Shows.—In reference to this subject, allow me to offer a suggestion, founded on long observation, and which is now made in the hope that it may be considered by the many benevolent persons who delighting in flowers, desire to encourage the same taste among their poorer neighbours. Judging from practical experience, I am of opinion that resident landlords who have influence in their neighbourhood would do much more good by giving small prizes to cottagers for improved culture in their gardens, both as regards vegetable produce and the display of hardy flowers, than by instituting flower shows, to which exhibits must be often carried a considerable distance, and at which persons receive prizes for one plant in a pot, or a nosegay of wild flowers, to obtain which Nature's gardens must have been robbed to a large extent, and their beauty impaired, destroying all prospect of increase by seed. Where this is the case, the gardens belonging to the successful candidates may not unfrequently be found very unworthy of reward, as it does not follow that the owner of one plant in a pot possesses a border of flowers, or a well-stocked plot of vegetables; but where the garden altogether is the object to be judged, emulation is excited, and one of the greatest benefits is obtained, viz., that of beautifying not only the separate homes of each individual, but adorning the whole locality in which they live, and enabling them by such competition to learn how to excel each other in friendly cultural rivalry.—C. [With these suggestions we wholly agree. Drawbacks and doubtful practices occur in connection with flower shows great and small. It is better in all ways to encourage good culture, good taste, and beautiful hardy flowers in small gardens, than to tempt their owners to compete at shows.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Christmas Roses Seeding.—I send you ripe seed-pods and a flower of Christmas Rose, which, judging from its size, and the large foliage of the plant, I am inclined to think is *Helleborus maximus*. I have two fine plants of it, planted in 1874, which this season have produced considerably over 100 blooms. When should the seed be sown?—WIRTON. [At once in pans in a frame facing the north.]

China Grass (*Behmeria nivea*).—Will you kindly inform me what is known of the China Grass, as it is termed, or Ramie Grass? Is it Urticaceous?—PРЕЖЕ ИСКУЛЬ. [It is a hardy herbaceous plant in the neighbourhood of London, attaining a height of from 3 ft. to 4 ft., further south it grows more freely, especially in warm, open soils. Still more suited to its wants is the climate of the south of France and the Channel Islands, the London climate not allowing the plant to attain its full growth. It belongs to the Order Urticales, or Nettlesworth.]

THE KITCHEN GARDEN.

IMPLEMENTS FOR POTATO CULTURE.

The popularity of the Potato as a subject for exhibition has naturally led to methods of improved culture, and this advance has been materially helped by the introduction of late years of the scarce and expensive American varieties, for the production of large crops from small and costly quantities could only be obtained by a high order of cultivation, and with it a much greater expenditure of time and labour than has commonly been bestowed upon this desirable esculent. Our American friends have also given us many useful and important hints with respect to their modes of culture, and, although generally from want of sufficient space and high rents we have hesitated to adopt the single-hill system so familiar to them, yet in the ridge system of cultivation we have a modification of it, and one more adapted to our insular practice and ideas. Still the great moving spirit of this anxiety for improved forms of culture has been a desire to produce fine exhibition tubers, it being a well-known fact that just in proportion as these are obtained so must the general crop be benefited. The negligent cultivator, who takes things in a hap-hazard fashion, is content to go on planting Potatoes after the same manner as his forefathers; and if his crop be half diseased or of inferior quality, he feels satisfied that he has done his best; but the Potato grower and exhibitor of the present day has learnt by his own experience, and from the teachings of his opponents, that if success be desired it must be earned, and that in no respect more thoroughly than in the necessary expenditure of labour involved in better cultivation. Year after year has shown that the ridge system is not only applicable to all kinds of soils but to all sorts of Potatoes, and that the apparent loss of crop consequent upon the wider space that must exist between the rows is more than compensated for by the extra produce, which is also of a finer quality, and, as a rule, less affected by disease. The ridge system requires that, for Potatoes having a short or medium haulm, the width between the rows should not be less than 3 ft., and for sorts having a tall or exceedingly robust haulm, from 3 ft. 6 in. to 4 ft.; and, wherever the soil is fairly good, and the seed tubers of picked quality, it will be found that this width is not excessive. One of the undoubted facts that recent discussion on the Potato disease has elicited, is that the rains wash the disease spores from off the foliage into the soil, and into contact with the young tubers, and by this means the tubers near the surface are most subject to the disease. When Potatoes are grown upon the ridge system, and the ridges are fully finished up in the summer, it will be found that as the haulm grows, by its own weight it falls aside into the furrows, leaving the top of the ridge somewhat exposed to the sun, therefore, when heavy rains come, the spores are washed into the furrows rather than on to the ridges, and the damage to the tubers is greatly lessened; moreover, the sharp pitch of the ridge prevents the entrance of much of the cold moisture, and the danger from disease is in this way considerably mitigated. The ridge system, indeed, presents so far the best practical embankment against the inroads of the disease.

The grower's first work in preparing his soil for the reception of seed Potatoes should be to have it dressed in the autumn with slackened lime and soot. If this mixture be allowed to remain in the soil during the winter, its fertilising powers will greatly increase, and many dangerous insects will be effectually destroyed. If forked into the ground as early as possible after the preceding crop is cleared great advantages will accrue, and later on a moderate dressing of thoroughly decomposed stable manure should be applied, so that some of its rawness may be removed before the seed tubers are planted.

For the moving and distribution of manure, no implement that has come under my notice is more useful, lighter, and better adapted for its purpose than the one now illustrated as No. 1; it can be used during a long day's labour without producing weariness; indeed, its very elegance almost tempts one to use it.

But manure, if short and well decomposed, needs also a shovel, to distribute it properly and make clean work. The

implement illustrated as No. 2 has singularly good qualities; it is not only light and elegant, but it is of great strength, for instead of the handle being fastened to the hose or sheath

No. 1.

No. 2.
Manure shovel.

No. 3.
Flat-tined digging fork.

by means of uncertain rivets, it has a stout centre worked into it after the manner of a cane-handled cricket-bat, and so bolted that any dislocation seems impossible. The manure being

No. 6.—American prong hoe.

spread, the soil should be deeply dug, either throwing it into ridges of the desired width, or leaving it rough but on the flat, according to the taste of the cultivator. If, however, the plan

Pointed shovel.

No. 8.
Potato digger.

centre spit being turned first, and the side spits placed upon that; in this way the ground is not only thoroughly exposed to the frost, but is also lined out for planting in the spring.

The flat-tined digging-fork, shown as No. 3, is at the same time one of the strongest and yet most useful instruments for digging that I have seen, being equally useful for every description of soil, but especially for stiff loams; it works clean, and leaves but few crumbs behind. I find labourers in this locality evince a decided preference for this fork over any of the ordinary cast steel type.

Where the soil is very loose and ashy a good spade is almost indispensable. The one represented at No. 4 is light in construction yet strong, and has an iron sheath well up the handle. Assuming that the ground is left in ridges, the next step will be, at some favourable time during March, to fork up the furrows to a good depth, mixing some of the pulverised soil of the ridges with them, and even later on forking might be repeated with advantage, working in leaf-soil, wood-ashes, guano, or any similar manure, so as to keep the soil as light as possible. At planting time a line should be strained down the centre of the furrow, and a shallow drill drawn; in this the seed tubers are carefully placed, and covered up with the fine soil on either side; when convenient the ridges are forked down and levelled, and in this condition the ground remains until the haulm appears.

Flat hoeing is an essential portion of Potato culture, as by it the ground is thoroughly cleared of weeds, and the surface is made ready for earthing. For this purpose the most suitable instrument is the crane-necked hoe, No. 5, which admits of the blade being worked well between the haulm without injury if the cultivator use but ordinary care; it is light and exceedingly useful, producing excellent results.

After the weeds are destroyed it is good practice before earthing to stir the soil well between the rows to the depth of 3 in. or 4 in., either with the fork or the American prong hoe (No. 6), singularly light and elegant, made by Hexamer, of the United States. This hoe, as seen in the illustration, is composed of three double tines that pass through a steel socket at the end of the handle, and are fastened by means of a key. Its width is about 10 in., and this can be reduced to 6 in. by taking out the outer tines. It is a splendid implement for surface-stirring in light soils, and is equally useful as an earther when the haulm is sufficiently high.

With the ridge system it is necessary to earth up two or three times, the fork being used for the major portion of the labour, making a neat finish by throwing the crumbs to either side with the pointed shovel, No. 7, the sides of which are slightly incurved to admit of its making a rounded furrow. When this work is done the crop must remain untouched until ready for lifting.

No. 8 represents a specially constructed Potato digger, the tines being slightly bent to admit of the tubers being well and cleanly lifted out of the soil; and if the crop be good no labour can be more pleasant or profitable than Potato digging. The implements illustrated—with the exception of the prong hoe—are manufactured by Messrs. Parkes & Co., of Birmingham, whose steel forks have been long and favourably known.

A. D.

Endive for Spring Use.—Early spring is perhaps the most difficult season for supplying good salads when there is not much accommodation in the way of pits, &c., for sheltering half-hardy crops, as the late crops are over, and the early ones are not sufficiently forward to be of much assistance. One of the most useful

crops that I have found for capability of enduring all weathers is late-sown Endive; it is usually sown here rather thinly, in drills 1 ft. apart, on a border of dry and moderately good soil about the last week in August. If the seedlings appear too thick to attain a reasonable size, they should be slightly thinned, but not transplanted, for the plants will be only about half-grown when winter arrives, and as soon as they commence to grow in spring the demand for them will necessitate the drawing out of the strongest in succession. Although easily injured by frost when fully grown, Endive during the first stages will resist frost as well as the hardest Cabbage Lettuces. The sorts I grow are the Green Curled and Batavian. As a safeguard against the effects of excessive frost, a light covering of branches or old Asparagus tops is extremely useful, but thick coverings will do more harm than good.—JAMES GROOM, *Henham*.

Mushrooms on the Walls of Turf Pits.—Having noticed in your last issue an account, quoted from THE GARDEN, of the singular Mushroom bed in Lord Lodesborough's garden at Norbiton, I (Mr. Geo. Cooper, in "Derby Mercury") here ask to be allowed to give a few remarks as to my mode of growing them. In growing Mushrooms I have a still more profitable object in view, namely, to get a quantity of good frames in which to grow thousands of plants. I get a supply of turves all cut about 12 in. by 18 in., and 3 in. thick. I then use the rule and line, and form a ground plan of what is termed a cool pit for plants; these turves are placed one on the other till the required height is reached, say 2 ft. back wall and 1 ft. front wall, the ends to slope from back to front; I get my wood-work frame—just the wall plates and a few rafters across from back to front—then the lights to fit, which makes the frame complete. Every turf is placed the Grass downwards, except the top layer, which should be placed the Grass upwards. In building these pits I place in every layer of turf a quantity of Mushroom spawn, in pieces about the size of an egg, and about 9 in. apart in the rows, and about 3 in. from the inside edge of the frame; the heat of the sun upon the glass will give the pit a healthy moist atmosphere, and cause the Mushroom spawn to spread and produce quantities of Mushrooms from the turf walls. I cut Mushrooms as late as November last year, and I commenced cutting from the same pits a month ago. A pit neatly and properly built will last eight or ten years, and produce Mushrooms every season quite eight months out of twelve. I have four large pits, over 100 ft. long, now to be seen at my nursery, Rose Hill, Derby, with thousands of bedding and other plants in the same pits. These turf pits are cool and moist in summer for plants, and, being nearly a foot thick of turf, are much warmer for plants in winter than brickwork. When a new pit is well made and cut round with a turf edging knife, and the top Grass trimmed neatly, it looks better and more pleasing to the eye than bricks and mortar.

Leeks.—There is certainly an unfounded prejudice against this most useful vegetable, for when good Onions are obtainable, Leeks are at a discount, yet why this should be the case I am at a loss to discover, for this reason, that for many culinary purposes they are decidedly superior, added to which they are far less liable to be affected by insects or disease than Onions, for while the onion-fly and mildew frequently make sad havoc in Onion beds, the Leek only requires good rich soil to ensure an abundant crop. There are several varieties, but one is ample for even the largest garden. I have grown London Flag, Henry's Prize, and Musselburgh, and found them all good and prolific kinds. Sow at the end of February, and transplant as soon as large enough into trenches like Celery, or make large holes, into which drop the plants, together with a little soil to hold them firm, and fill up as growth progresses. Besides being they require no further attention, and are fit for use any time during the winter; but, as before stated, it is late in the spring—when old Onions are comparatively worthless, and those sown in the autumn are not large enough for culinary use—that Leeks are most appreciated, as they continue in good condition until June, and, if taken up and laid in a cool place, even later.—J. GROOM, *Henham*.

Radishes, Good and Bad.—It is odd that among the quantities of home-grown Radishes sent to our markets one never sees any of the young and tender samples common abroad; on the contrary, they are like little Turnips. It, however, private growers would accustom us to Radishes gathered at a proper age, and without the woolly fibre and roughness of flavour characteristic of the Radishes of the shops, perhaps we should in time see the market supplies improved.—Y.

Market Gardens in San Francisco.—These are in the suburbs of San Francisco, and are in the hands of Chinamen, or of Italians who in this work compete successfully with the former, and the plots of ground of both races are marvels of careful husbandry. Wooden conduits, on trestles, carry the water raised by windmills from wells to every part of the garden; and the Chinaman, not content with this general irrigation, goes to every particular Cabbage and Lettuce, watering-pot in hand, and washes it as painstakingly as if it were a costly exotic. His reward is great in the size and healthiness of his vegetables.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE noblest flowers of the week are the earliest forms of the German Irises, with great Orchid-like blossoms, growing freely on almost any soil. Among these, the finest is one called spectabilis, a variety of *I. germanica*, with dark and rich hues. The variegated forms, like *I. Victorine*, and the rich yellow and dark kinds are a little later in opening. The Narcissus-flowered Anemone is one of the kinds not usually placed among the very finest, but of late its character is better shown through the plants getting stronger, and the effect of the flowers during the past week was most pleasing and quite distinct in aspect from any other kind. The plant deserves a place in the choicest collection. The graceful-looking *Hyacinthus amethystinus* is still in great beauty, a most precious May border-flower. The Californian *Delphinium nudicaule* has been for some time a conspicuous flower in many gardens; the variety of this, called *D. nudicaule elatius*, is, as grown at Crowsley Park, a distinct improvement on the original form, excelling it in stature and brilliancy of colour. The transparent white blossoms of the St. Bruno's Lily (*Anthericum Lillastrum*) now adorn many gardens, and a fine companion plant to it, and somewhat like it in habit, is the handsome blue Quamash (*Camassia esculenta*), which is now becoming plentiful about London. It is noteworthy that the

Cyclamen-leaved Anemone (*Anemons palmata*).

Iris are now blossoming freely in the open ground in Barr's Nursery, where they have now remained two seasons undisturbed. The beds are raised a little above the level, and the soil is warm and well drained. There are so many bright hardy flowers appealing to us for notice now-a-days that our old friends the *Aubrietias* are almost forgotten. At Crowsley Park, however, the other day we were surprised to see an *Aubrietia* (*A. Hendersoni*) with almost the richness of one of the new *Pansy-Violets*. This kind is as great a gain as if it were a new species, it is so widely different from the usual forms of this fine rock plant, although it is itself but a variety, and we should say one of the best hardy plants ever sent out by Messrs. Henderson. The various *Thriffs* are very beautiful now; the white variety of the common *Thrift* is perhaps the most valuable of all, because its foliage is of such a fine fresh green in winter. The great Oriental Poppies are now in their most gorgeous dress, and they are certainly most effective objects in the garden, but they are among the kinds that may be easily overdone. An irregular group in the distance in the picturesque garden, or a few plants well placed on the margin of a shrubbery in the small garden, will suffice. The old and common way of dotting a plant all over the place because it happens to be a showy one must be given up if we desire to avoid weak, spotty, incoherent, and monotonous effects in the garden. Among the more uncommon flowers of the week we noticed the blue *Lithospermum Gastoni* at Crowsley Park; it seems a slow grower and dwarf, and therefore suited for the rock garden. Some of the species of *Iris*, such as *I. subbiflora*, are in bloom in Osborn's Nursery at Fulham, where rare bulbs and many other hardy plants of great merit, that are not common in gardens, may from time to time be found.

Whorled Pentstemon (*Pentstemon procerus*).

Golden Poppy (*Papaver croceum*).

Dragon's Mouth (*Arum crinitum*).

Clustered Campanula
(*Campanula glomerata*, var. *speciosa*).

Jacob's Ladder (*Polemonium caeruleum*).

Narcissus-flowered Anemone (*Anemone narcissiflora*).

Alpine Erinus (*Erinus alpinus*).

Rosy-red Geranium (*Geranium laucastriense*).

St. Bruno's Lily (*Anthericum Liliastrum*).

Eastern Poppy (*Papaver bracteatum*).

Creeping Gromwell (*Lithospermum purpureo-ceruleum*).

Rosette Mullein (*Ramondia pyrenaica*).

THE FRUIT GARDEN.

PEACH CULTURE NEAR THE SEA.

A CORRESPONDENT asks (see p. 496) for information respecting outdoor Peaches near the sea-coast, and as the gardens here are within three miles of nearly the most eastern point of East Suffolk, we experience the evil effects of cutting winds as much as in any other part of the kingdom; in fact, they are much more disastrous to spring growth than frost. In the few places where Peach culture is attempted close to this coast the past month has been most disastrous, not only to Peach trees, but also to much hardier-foliaged trees, for when exposed to the full force of the gales Rose-bushes, and Pear and other wall trees become withered as if a scorching flame had passed over them, owing to the persistency with which the wind has blown from the sea. We are, however, well protected on all sides by means of lofty trees, and as regards general health and regularity of cropping two long walls here devoted to Peach and Nectarine culture will, I think, bear favourable comparison with walls furnished with the same kinds of fruits in the southern or western counties. Like your correspondent, I believe that not only gumming, but that many of the ills to which Peach trees are liable are due to atmospheric influence; for, although we get here such ungenial springs we generally get dry autumns; therefore, although the annual growth is not so luxuriant as in the milder western counties, we can safely rely on getting it thoroughly matured, a point of the greatest possible importance in Peach culture, whereas the soft mild air of the south and west induces late growth, and when the wood is over-strong and but indifferently ripened frosts greatly affect the trees, bursting their saps-vessels and considerably impairing their general health. As regards the system which we adopt, I have only to say that we train the wood close to the wall in the old-fashioned way, with nails and shreds. Our trees are all fan-trained, and each covers from 20 ft. to 30 ft. of a 12-ft. high wall. The alleys, which are 3 ft. wide, are mulched at this season, and while the fruit is swelling, copious supplies of water and of liquid manure, if the crop be heavy, are given, but as the fruit begins to ripen, these are withheld. Covering and uncovering are strictly attended to until the trees are well clothed with foliage and all danger from frost is over. The principal point is to get the current year's wood into good growing condition as soon as possible by paying early attention to disbudbing, picking off all blistered leaves, and washing the trees with soap-suds and clear water by means of the garden engine. The young growths should be trained in moderately thin, so that every leaf may get the full benefit of the light, and the fruit should be thinned by degrees. We never stop the annual growth, except in the case of a gross shoot that is robbing the others, and if there be a weaker shoot to fill the vacancy, we cut the over-luxuriant branch out altogether. Even after one of the most trying springs on record, we have now such heavy crops of both Peaches and Nectarines on open walls, that plenty of thinning is still required. J. GROOM.

Henham Hall, Suffolk.

FUNGI AND FRUIT DISEASES.

Fire Blight in the Pear.

THAT this is of fungoid origin is now clear from the researches of Dr. J. Gibbons Hunt, President of the Biological Section of the Academy of Natural Sciences of Philadelphia, an excellent botanist, and one well skilled in microscopy. He finds that a very minute fungus germinates on the outer bark, enters the structure, destroying the cells as it goes, till it reaches the albumen, and then it penetrates right to the pith by way of the medullary rays, totally destroying the branch from centre to circumference. Dr. Hunt was not one of those who believe much in fungoid diseases. Indeed, if he really had any prejudice at all, he was impressed with a presumption that the fungus found in Pear blight was but a follower of diseases. But there is no other conclusion than that arrived at by him, viz., that in the true fire blight fungi are the cause of the disease. The fire blight attacked large branches, destroying them rapidly, because all connection with sap-collecting roots was cut off; but there were numerous diseases of the Pears similar to fire blight, although

not so destructive, because the fungus did not penetrate sufficiently deep to sever all connection with the roots. It may be that fungi causing these appearances are forms of the other fungus, for it is now known that many characters are assumed at various stages of growth by these little plants which we know as fungi. One of these diseases appears as a sort of bark scaling at a period anterior to that when the Pear becomes naturally rough-barked, which is not till its twelfth year. This does not penetrate deeply enough to affect seriously the inner bark. Still that it has a bad effect on health is apparent from the fact that trees with it have their leaves turn a red or brown colour early in the autumn, showing that their nutrition has not been perfect. Another form attacks the green bark of five or six-year-old branches, making dead patches of an inch or more surrounded by the healthy green bark. Where the destruction terminates there is a separation, and the appearance is just as if the irregular patch had been marked by the edge of a knife. Still another form seems to confine itself to the spurs; it eats out the structure at the junction with the main branch, and gives the tree a peculiar appearance—dead leaves and spurs everywhere, while the main shoots and branches are as healthy as they can possibly be.

Cracking in the Pear

was also often caused by a fungus. I have had no chance to get the case I am now about to refer to microscopically examined, but there are some attendant phenomena which stamp it as clearly of fungoid origin. Early in summer, the leaves still appearing quite healthy, pale spots may be noticed in the leaves when held up to the light. There is some change going on in the cellular matter. It soon dies, and there are black spots on the leaves. The leaves are fully expanded by this time, and the disease remains as black spots. Now the fruit we call a Pear is, morphologically, but a bundle of leaves. The germ of the disease is therefore as early in the fruit as in the leaves. It develops in the growing fruit at the same time as it is developing in the leaves; it destroys the outside just in the same way. But the fruit is different from the leaf; it keeps growing on; the dead portions cannot grow, and so there is no alternative but to crack. There are of course other causes that are not fungoid which lead to cracked fruit. He had seen *Beurri Giffard* crack through to the core, it seemed almost in a single night, but the peculiar form of cracking he referred to certainly came from the destruction of the outside in spots, by what had all the appearance of minute fungi. There was yet another fungoid disease, known as the leaf blight, and this was particularly troublesome to the raiser of seedling Pears in places where the land was liable to get very warm in the summer. The little fungus was easily seen under a common pocket lens, and very beautiful it was. When mature it was like a miniature volcano, with the crater beautifully fringed around the outer edge. I believe this is one of the stages or forms of *Rastelia cancellata*, and I think it will only germinate so as to be in the injurious condition we find it, when the thermometer under ground rises above 75°. At any rate, if we sow Pear seeds among Wheat, among Apples, or other strong growing plants, under a little brushwood—or under a shaded hot-bed sash—or in any place where the ground does not get very hot, this fungus does not prove troublesome.

Apple Blight.

The fungoid diseases of the Apple have not hitherto proved very troublesome, but there is one which is evidently allied to that which causes fire blight in the Pear, only that it appears to confine itself to the one or two-year-old branches, instead of those of more advanced age. It is of western origin. I saw it first in Illinois about ten years ago, and though I have travelled extensively over most of the country, I am pretty sure that it had not crossed the Alleghenies at that time. Since then it has gradually made its way eastward, and in 1874 I saw it for the first time in Southern Maryland. So far I have not seen any in Pennsylvania. This season at Windsor, Canada, I saw an orchard suffering as badly as any Pear orchard, and with all the symptoms of true fire blight, large as well as small branches suffering alike. In the same orchard also was some spur blight as before described among Pears. I have little doubt these are all forms of the same fungoid development, and the same in the Apple as in the Pear.

Peach Yellows.

In the Peach the worst form is that which produces the disease known as the yellows, and here I would again remark that we must not look to one cause alone as producing disease. That a fungus will produce the yellows I am satisfied, but I am by no means satisfied that all Peach trees with the yellows are so diseased through fungoid agency. I was first led to suspect that fungi would cause yellows by having some White Spruces growing on a piece of land where some English Alders had been grubbed out. Fungi grew on the

decaying Alder roots, and spread to the roots of the Spruces, and in all these cases the plants assumed a golden sickly hue. The ground dug up about them had a Mushroomy smell, and with a lens the Spruce roots could be seen in the snake-like folds of a thready fungus, and all the young fibres so attacked died, leaving only the coarser roots alive to do all the active work. Some shovels full of this earth placed at the roots of the Norway Spruces produced the following year the same yellow sickly tint in them, and I have some of them left yet to show to my friends as examples of their destructive effects. Since then I have dug up around the roots of Peaches with the yellows and have found a thready fungus, Mushroomy smell, and dead fibres, just as in the diseased Spruces. Of course other things as well as fungus must produce a disease like this. If a plant be growing on wet ground the young fibres rot and the leaves become yellow; or where the trees do not rot, but the ground is poor, then also is there a yellow tint. In the one case the plant cannot eat, in the other there is nothing to eat; the yellow tint is alike in both, but in the case of the fungoid attack the element of the fungus is apt to pervade all the plant's system, even to penetrating the buds and seeds, so that it may be propagated and carried to distant localities.

Grape and Gooseberry Mildew.

It is much with the Grape as with other fruits, fungi are sometimes the cause as well as often the consequence of disease. There is no doubt whatever that anything that will injure the roots of a Vine, whether it be *Phylloxera*, over-dampness, extra-richness, or other causes, will result in fungoid diseases to perhaps both fruit and Vine, but the labours of intelligent men in the matter of the Vine mildew leave no doubt that Vines in every way healthy can fall a prey to this destructive pest when it once gets fully under way. I cannot go over the whole ground of fungi and fruits, but will just refer very briefly to the mildew on the Gooseberry. This attacked certainly healthy trees, though, like the leaf blight on seedling Pears, it never was troublesome, except where the soil was heated to a higher temperature than 75°. If corn-stalks, stones, or even old boots and shoes, as I have seen, be piled up under a Gooseberry bush, so as to keep the soil cool, it will never mildew. I think that the few facts which I have given prove that fungi are often the cause as well as the concomitants of fruit diseases.

Discussion.

Mr. C. M. Hovey remarked that Mr. Meehan had somewhere said that fungi liked to grow in cool moist places, but he now seemed to say that they only grew where the temperature was over 75°. How could these confusions be reconciled? Mr. Meehan replied by asserting that there were different species among fungi, and just as some flowering plants lived in the arctic and some in the tropics, so did different fungi seek different temperatures for their development. Mr. C. M. Hovey further said that fungi had nothing to do with Pear cracking. He had been a cultivator of the Pear for over forty years, and he had noticed that when there was an extra wet season, while the fruit was swelling, cracking prevailed to a greater extent than under any other circumstances; and the reason of this was plain—the roots continued, there was little evaporation, by the peculiar condition of the atmosphere, there was little evaporation going on, and thus more moisture was drawn into the plant's system than the plant required, the tissues then became distended and had to burst. It was then that fungi followed, and they were therefore the followers of diseased conditions and not the cause. He would say that cracking in the Pear was due to unfavourable climatic conditions, with which fungi had nothing to do. Mr. Meehan replied that he thought he had already made allowances for such cases as Mr. Hovey alluded to. The only difference between himself and his friend was that while he thought there were many causes of cracking and other diseased appearances, Mr. Hovey seemed to think there could be but one. We know both had nearly the same result, and so a crack in a Pear would sometimes precede disease from perhaps climatic causes, while at others, as he had already shown, the fungus preceded and caused the disease. In regard to the young Pear fruit absorbing more water than it could hold as a cause of cracking, Mr. Meehan said, it was pretty as a theory, but rather an improbable one. Mr. Hovey's Pears might possibly burst if nature attempted to put its quart of sap into a pint of Pear, but then it is necessary to know that nature really does attempt these impossible things. Mr. Harrison stated that he had known of fruit of the White Doyenne which had commenced to crack before fully grown being made to ripen free from all blemish, by the application of a heavy dressing of ashes as soon as the fruit began to crack. Mr. Sylvester, who has paid great attention to all matters connected with fruit culture, said he had failed to be successful in a like experiment.—THOMAS MEEHAN, in "Proceedings of an American Pomological Society,"

Early Grapes in Pots.—These are now greatly appreciated on the dessert table, and therefore we should exert ourselves to supply them. Some assert that to start pot Vines early in the autumn is a disadvantage, which it certainly is if the Vines have not been thoroughly ripened and prepared for the work beforehand by starting them early and getting them well matured by the middle of August, in order that they may be placed behind some sheltered wall with a north aspect. This gives stamina both to fruit and foliage, and the buds are more easily excited into growth by heat and moisture than they otherwise would be. Pot Vines, when started early, should be plunged in a bed of fermenting material, watching carefully that the heat does not exceed 85°, or otherwise it does more harm than good, by weakening the roots instead of strengthening them. Growing Vines in pots says the permanent Vines, and although the fruit may not be so large as that on established rods, still good average produce ought to be obtained from Vines in pots, and they can afterwards be thrown away and young ones raised every year.—JAMES SMITH, *Waterdale*.

Raspberries and their Culture.—Can any one say whether the old-fashioned Raspberry called the Antwerp fifty years ago is in existence or not? I am aware that the name Antwerp Raspberry is still recognised, but if I am to judge by the fruit seen under that name it may truly be said that it is not that of the old Antwerp, which was very large and conical, and equally good in white and red, but the most delicate flavour was that of the white kind; otherwise they were equal as regards size, the clean manner in which they grew, the abundant crops which they produced, and the desirable peculiarity of slipping off the foot-stalk when gently gathered without the slightest escape of juice or adhesion of the fruit to the centre. What is the best method of obtaining plentiful crops of Raspberries?

—L. [The red and yellow Antwerp are still grown under these names, and may be procured from any good fruit nursery. Whether they are the old Antwerp varieties about which your correspondent inquires I am unable to decide, but they have been both superseded by other sorts, such as the *Fastoff*, *Prince of Wales*, and *Carter's Prolific*. I never heard of a white Antwerp Raspberry being in cultivation, but there is a sweet yellow Antwerp grown, which may be the variety alluded to as having such a delicate flavour. The most certain mode of growing good crops of Raspberries is planting them in soils made very rich with rotten manure, and as the plants are surface-rooters they ought never to be dug near with the spade which destroys their fibres. They should, however, be top-dressed every year with litter and well-watered during spring or summer droughts before the fruit is ripe.—T.]

Apricots as Standards.—Hitherto the cultivation of Apricot as standards has been of rare occurrence, even in the southern counties, where the fruit is apt to be deteriorated in quality when grown on south walls, and rarely attains that luscious richness of flavour which fruit obtained from standards generally possesses. Why, then, are bush or standard Apricots not more generally grown in favourable localities? The soil best suited to the Apricot is a calcareous loam or sand, of sound texture, 2 ft. deep. It is of primary importance in preparing the sites for standard trees that the subsoil should be perfectly drained and the position slightly raised so as to elevate the stems above the ground-level. This will be found indispensable to success in places where the ground is at all wet. Moreover, the digging of the surface anywhere near the tree should be studiously avoided, as not only does such a practice destroy the surface-roots, but, more particularly in the case of standard trees, it has a tendency to retard fructification. Some of the finest and healthiest trees I have seen have had their roots wholly under gravel walks. Rich, deep clay soils are to be avoided, as they induce vigorous growth and imperfectly-ripened wood, the principal cause of the unfruitfulness often complained of in Apricot trees. When such soils have to be dealt with, a large percentage of old mortar rubbish may be added to them with the best results.—G. WESTLAND.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Rust on Grapes.—My Grapes are about the size of Peas and affected with rust: what can I do to get rid of it?—F. H. [Nothing will remove rust when once it gets on Grapes; try to find out the cause of it and endeavour to prevent its occurrence in future.—J. S.]

Early Ascot Frontignan Grape.—This Grape, of which a description and plate were given in THE GARDEN last February (see p. 180), received a first-class certificate at a horticultural exhibition at Reading on the 18th inst. The class certificate at a horticultural exhibition at Reading on the 18th inst. The specimen in question had been grown in an early Vinery with the Black Hamburgh, and was some days earlier in ripening than that variety. The bunches were medium sized, and well furnished with attractive-looking plump berries, which had a rich Frontignan flavour.—W. N.

PLATE XXIII.

THE LADY'S SLIPPERS OR CYPRIPEDIUMS.

(WITH A COLOURED FIGURE OF CYPRIPEDIUM NIVEUM).

Drawn by H. NOEL HUMPHREYS.

Of the different species belonging to this genus, all, both hardy and tender, are favourite garden plants. They are widely distributed in both hemispheres, and in all kinds of climates, from the north of Europe, and North and South America, to Japan, India, Borneo, Java, and the Philippines. In the whole family of Orchids, there is perhaps no other genus which has a wider range. Botanically, Cypripediums are distinguished by their having two fully-developed anthers, and the lateral sepals connate, or fused together, there being only one solitary exception in *C. arietinum*, whilst popularly they are readily known by their slipper-shaped lip. One tolerably well-marked section, all the species belonging to which being tropical American, has been made by the younger Reichenbach a separate genus—*Selenipedium*—but in the following remarks I have grouped all the species under the older and better-known name of Cypripedium. The different species of Cypripediums are nearly as diverse in habit and mode of growth as they are in their geographical distribution; all the hardy, and some of the tropical American tender kinds, are strictly terrestrial; others have been found clinging to the face of sunny limestone rocks in Moulmein and Burmah, while *C. Lowii* belongs to a group which is strictly epiphytal. The culture of all the tender species is by no means difficult, but that of the hardy North American and Siberian kinds is just the reverse, and many have failed to get such plants to bloom, except during the first season after they have been imported. The best results have been obtained with *C. spectabile*, *C. humile*, and *C. pubescens*, while Messrs. Backhouse have succeeded in flowering the rare and beautiful *C. guttatum* and *C. Incepeanum* in their nursery at York, where a broad patch of the only British species, *C. calceolus*, also does well on rock-work.

Propagation.

All the species are stemless herbs, and are readily propagated by dividing strong established masses; such off-shoots soon make blooming plants. Several beautiful new hybrids have been raised by Mr. Dominy and Mr. Seden in the Royal Exotic Nursery, at Chelsea, and also by Mr. Cross, gardener to Lady Ashburton, at Melchet Park, in Hampshire, after whom one of the hybrids is named. Other cultivators, including Mr. Pilcher, gardener to Stigsmund Rucker, Esq., at Wandsworth, have raised seedlings from the chaste little *C. Schlimmii*, but these are said to vary but little from the parent plant. In order to obtain seed it is necessary to fertilise the stigmatic surface of one flower with the glutinous or honey-like pollen from another flower of the same plant, or from a separate species, if a hybrid be desired. The stigmatic surface in this genus is concealed by the infolded margins of the lip, and is, generally, a thick trowel-shaped ivory-like process just below the broad shield-like sterile anther, or staminode. Press down the lip and apply the pollen to the under side with the point of a pencil, or a quill tooth-pick will serve admirably for this purpose. The seed resembles fine mahogany sawdust, and should be sown as soon as ripe on the surface of living Sphagnum Moss that has become thoroughly established on the surface of a pot of fibrous peat; cover partially with a bell-glass, tilting it at the bottom so as to allow a free circulation of air. This last precaution is especially necessary just when the young seedlings make their appearance, as that is the most critical period of their growth, and many thousands of seedling Orchids never get beyond that stage. As the seedlings develop themselves they may be removed and potted off separately, and treated as recommended for established plants.

Culture of Tender Species.

These should be potted in a fresh open compost, consisting of fibrous peat broken with the fingers into lumps about the size of pigeons' eggs; to this add about one-fifth of either dried horse or cow manure, which should be collected in pastures in summer when dry and laid on a hot fire long enough to kill all insect life that it might contain. A little

turfy loam may also be added in the case of the most robust-growing species, adding sufficient coarse well-washed sand or grit to keep the whole porous. The pots or pans in which the plants are to be put should be well washed and thoroughly dried before they are used, and this remark also applies to the crocks employed for drainage. Cypripediums do not require so much drainage as many other Orchids; indeed, about one-third the depth of the pot or pan will be amply sufficient for them. Place a thin layer of fresh Moss, or the rough fibre from peat, over the crocks so as to prevent the particles of compost being washed down among the drainage. The collar of the plants may be about level with the rim of the pot, and the compost should be neatly surfaced with fresh Sphagnum, which should be kept regularly sprinkled with spray from a syringe, so as to induce it to grow as freely as possible. All the species require a copious supply of moisture when growing, both overhead and at the root, and they should never be allowed to become dry, as they, like many other stemless Orchids, have no decided season of rest. During the spring, summer, and autumn months they should all be regularly syringed morning and evening; and, in exceptionally hot dry weather, a gentle dewing in the middle of the day will induce that healthy vigour and fresh succulent growth so pleasing to the eye of the practical cultivator. They should be shaded carefully from hot sunshine, and free ventilation is essential, care being taken to guard the more tender species from cold cutting draughts. All these plants are more or less liable to be attacked by insect-pests, especially if out of health through any irregularity in their treatment. Thrips, red spider, and the yellow aphides peculiar to Orchid-houses must all be guarded against by means of a liberal use of the syringe and abundance of fresh air. If, however, thrips and fly have obtained a foothold, eradicate them at once by repeated fumigations with Tobacco-cloth or rag. It is better to fumigate gently on two or three successive evenings than run the risk of burning the foliage by filling the house to full of hot smoke. If the plants be gently sponged over occasionally with clean tepid water, it will do much towards keeping them free from dust and insects. Some recommend the use of weak liquid-manure when the plants are making their growth, but beginners had better avoid such applications. Many of the species grow well in a moderately warm greenhouse temperature or in a Cattleya-house, but *C. Stonei*, *C. laviatum*, *C. concolor*, *C. niveum*, and one or two others, do best in the warm, moist atmosphere of a stove or East India house. The pretty little *C. Schlimmii* does best in a cool house with Disas and Odontogloss, and requires careful attention to prevent its suffering from thrips, which seem to have a special liking for its fresh succulent foliage.

Descriptive List of Select Kinds.

Handsome Lady's Slipper (*Cypripedium venustum*).—This is an old and well-known plant, with handsome foliage and rather showy green and purple flowers, which are copiously produced during the autumn and winter months. The flowers are nearly as large as those of the Bearded Lady's Slipper, but different in the foliage; and the lip is bronzy-green, not deep purple, as in the last-named plant. Close examination of the leaves shows them to be covered with a superposed layer of air-cells, and these give to the foliage a rather glaucous tint. It appears to like a tolerable degree of warmth; but I have seen creditable plants grown under ordinary greenhouse treatment. The sepals are white, or pale green, striped with darker lines at the base; and the spreading petals are olive-green at the base, having purple apices. They are fringed by rather long black hairs, and have a few black spots over their surface. It is an easily-grown plant, that should be in every collection of greenhouse or stove exotics. It is a native of the East Indies.

C. venustum var. *spectabile* is a very distinct and bright-coloured form, although very rare. There is an excellent coloured figure in Vol. II. of "Warner's Select Orchidaceous Plants," t. 24.

C. pardinum is a distinct variety of this plant, characterised by its broader foliage, having paler blotches of purple behind, and in the toe of the slipper being peculiarly obtuse or blunt. It often bears two, and more rarely three, flowers on a scape, the colours being similar to those of the normal form.

Self-coloured Lady's Slipper (*C. concolor*).—This is a small, but very distinct and interesting species. The flowers, which are of a clear sulphur-yellow throughout, sparingly dotted with brown, are

WHITE LADY'S SLIPPER (CYPRIPEDIUM NIVEUM)

borne on one or two flowered scapes from 2 in. to 5 in. in height, the flowers themselves being 2 in. or 3 in. across. It grows best in a warm moist stove or East Indian house, planted in a shallow pan of fibrous peat and lumps of sand or limestone rock. It flowers nearly continually when well grown, and requires plenty of moisture during the summer months. In winter water very carefully, as it is inclined to rot off at the crown. The plant was discovered by the Rev. C. Parish on limestone rocks in Burmah. It is also a native of Mouleim, where, according to Colonel Benson, it is found on the exposed face of limestone rocks, under a burning sun for a considerable portion of the year.

Snow-white Lady's Slipper (*C. nivium*).—This is a little gem, and a general favourite wherever it is grown. In habit, it is so near the last that Mr. Ellis, who obtained many of the first plants introduced, mistook it for *C. concolor* until it flowered. The foliage is, however, a little longer, and rather deeper in colour; the flowers are borne on one or two flowered scapes, which vary from 3 in. to 6 in. in height, sometimes even higher; the sepals are white in front, suffused with delicate rose-flesh at the base, which gives them a charming opaline appearance, and at the back they are suffused with green, and blotched with dull purple; the sepals are pure white, nearly 2 in. long, and are dotted at the base with purple; lip oblong, slightly pointed, not unlike a wren's egg, but larger, pure white, with minute purple dots. Like the last, it luxuriates best in a warm, moist atmosphere, and thorough drainage at the root. Different individuals of this pretty little plant vary considerably in the form of the lip, some having the lip tapering and bluntly pointed, as in *C. concolor*; while others have it rounded, something like *C. Schlimii*. It so nearly resembles *C. concolor* in all its parts, that I am inclined to think it is best considered as but a white form of that species.

Javanese Lady's Slipper (*C. javanicum*).—This is a small species of the *C. barbatum* type, having variegated foliage and solitary dingy green and purple flowers on a long, slender, purplish scape. It grows, well treated, like *C. barbatum*, and flowers during the winter months; its flowers, like all the others in this group, being very permanent in character. Although not showy, the plant is worth adding to a collection of these plants for variety. It is a native of Java and other islands in the Indian Archipelago.

Bearded Lady's Slipper (*C. barbatum*).—This is one of the best known and most generally cultivated of all the species. It is a most vigorous and free-flowering plant that may be had in bloom all throughout the year with but little trouble. The foliage is of a pleasing green colour, with darker blotches and lines, the flowers being borne on long deep purple or chocolate-tinted scapes, 6 in. to 15 in. in height. The upper sepal is fully expanded, clear white at the apex, its lower half being striped with deep purple and bright green. The petals are spreading, and are of a bright purplish tint, ciliated along their edges, and characterised by bright, hairy, black glands along their upper margins. The lip is quite an inch in width in good varieties, and of a deep claret-purple, with deeper veins. This is one of the most variable plants in the whole group, the typical form being somewhat caulescent in character, with very small and poorly-coloured flowers. The best known variety in cultivation, and one of the most popular for show purposes, is *C. barbatum nigrum*, or, as it is sometimes called, *superbum*. Another form, which bears two flowers on a scape, is named *C. barbatum biflorum*. *C. Crossii* is another very distinct form, and rather rare. Strictly speaking, *C. Veitchii* (*superbiens*) and *C. Dayii* may be referred to this species, and all the numerous forms are easily recognised by the peculiar marginal glands on the petals, and the shape of the green staminode. The plant, being robust, readily adapts itself to very diverse modes of treatment. It grows well in turfy loam, peat, and dried cow-manure in shallow pans or pots, and, when well-grown, makes a fine exhibition plant. For the latter purpose it is a usual practice to grow the plants in small pots, and arrange those that bloom best in a large pan when in flower. Grouped in this way, and neatly surfaced with fresh Moss, they have a fine effect in the eyes of ordinary floral critics, although they look stiff and formal to the artist. The plant is a native of Mount Ophir, a locality very interesting, as being the habitat of a beautiful, but, as yet, unintroduced Fern (*Matonia pectinata*).

Eye-like Spotted Lady's Slipper (*C. Argus*).—In habit this plant resembles *C. barbatum*, but the flowers are borne on taller scapes, the latter varying from 12 in. to 18 in. in height. The flowers are about the same size as in *C. barbatum*; sepals, white, streaked with green lines, as in *C. venustum*; petals, curved, as in *C. Fairieanum* and *C. vexillarium*, oblong, marked with green lines, and profusely spotted or blotched with deep purple eye-like markings; each petal has about seven large shining hairy glands along its upper margin, a character which shows its close relation to the bearded Lady Slipper in a marked degree. The blunt apices of the petals

are suffused with purple as in *C. venustum*. Lip like that of *C. barbatum* in form, but veined with green on a bronze-coloured ground, as in *C. venustum*. It is a distinct and handsome plant, growing and flowering very freely in the winter and spring treated like its congeners. It was introduced by Messrs. Veitch, and first exhibited in December, 1873. It is a native of the Philippines, and may be a natural hybrid. Mr. Bateman suggests that *C. barbatum* and *C. venustum* are the parents, and in this opinion I fully agree.

Purplish-flowered Lady's Slipper (*C. purpuratum*).—This, at first sight, so closely resembles *C. barbatum*, that it is not unfrequently so named in gardens and nurseries. It is, however, very distinct, and characterised by the absence of marginal hairy glands, and by having the margins of the acute dorsal sepal or standard very distinctly revolute. It is an old species, seldom seen in modern collections, although I have noted it flowering annually in the Kew collection for several successive years. It blooms during the winter months, and lasts for fully a month or six weeks in perfection. It sometimes, though rarely, bears two flowers on a scape.

Lady Hooker's Lady Slipper (*C. Hookeriana*).—This, although not remarkable for the beauty of its flowers, is a handsome plant, well worth growing as a foliage plant, its broad green foliage being conspicuously marked with silvery grey. Each leaf is from 4 in. to 6 in. long by about 2½ in. in width. The flowers are borne singly on scapes 12 in. to 16 in. length; sepals, ovate, of a greenish-yellow colour; petals, 2 in. to 3 in. long; spatulate, green at the base, and of a lively purple colour at their apices, the petals are spotted with purple or brown about the centre; lip, more or less swollen, of a greenish-purple colour; staminode, oblong, greenish. This is the best of all the variegated kinds, and good varieties bear really handsome flowers, while others are very dingy. *C. Bullenii* is a variety of this plant. Like all the other tropical species it likes plenty of subdued light and a warm, moist atmosphere. This species and *C. Fairieanum* are subject to the attacks of thrips and red spider if irregularly treated, and these soon spoil their beauty and give them an unseemly, rusty appearance. Genial warmth, fresh air, and moisture will do much to keep these pests in abeyance, especially if the syringe be freely used at the same time. It is a native of Borneo and the Malay Archipelago.

Superb Lady's Slipper (*C. superbiens*).—Although nothing more than a fine form of the Bearded Lady's Slipper, this is at the same time so distinct and beautiful, that for all garden purposes it merits a distinct title. The plant is easily recognised, even when not in flower, by its bright yellowish-green darkly-blotched foliage. Its flowers are large and solitary, borne on stout scapes, 12 in. to 14 in. high. The upper sepal is broadly egg-shaped, of a greenish shade at the base, softening into white at the tip, and streaked with deep green, convergent lines. Petals, 3 in. to 3½ in. long, nearly an inch broad, strap-shaped, rather blunt at their points, and deflexed at an angle of about 45°. The petals are white, shading into green at the base, the apices being tinted with rose. The petals are spotted throughout with deep purple, something in the way of *C. argus*; but here the markings are smaller and the segments larger. The lip is large, inflated at the mouth, tapering in graceful curves to a blunt point, being of a dull purplish-brown colour, veined with green at the sides. The stamina is lamulate, with a tooth on each side below. It likes a very warm, humid atmosphere, and a fresh, open compost, and appears to grow nearly all the year, so that it should not want for moisture at any time. It is a native of Java, often called *C. Veitchii* in gardens.

Mr. John Day's Lady's Slipper (*C. Dayanum*).—This is another fine and distinctive form of the ubiquitous *C. barbatum*, and as one of the most effective of its class should find a place in the most select collection. In form the flower reminds one of *C. superbiens*, but it is easily distinguished from that form by the dorsal sepal being narrower and more sharply pointed; the petals are longer and more spreading, and are not spotted. The upper segment is ovate, pale yellowish-white, streaked with green; petals, 3 in. to 4 in. in length, white at the tips, pale green at the base, streaked with interrupted brownish-purple lines. Lips very large and wide at the mouth, gradually curving to a bluntness point, as in *C. superbiens*, the colour being purplish-brown, margined with a darker of green. Foliage, light green, blotched irregularly with a warm, fresh, shade. It has a tolerably free habit, and requires a warm, fresh, humid atmosphere, with a copious supply of tepid moisture at the root. Flowered first about 1860. It is a native of Borneo and the Malay Archipelago. Although described as *C. spectabile*, it must not be confounded with the hardy North American species of that name.

Bannered Lady's Slipper (*C. insigne*).—This is one of the oldest and best of all the species, and one that grows well with the same care as is requisite to succeed with a *Fuchsia* or *Geranium*. It

is one of the best and most suitable of all greenhouse Orchids, for it must be badly treated, indeed, if it refuse to grow and bloom. It likes a compost of fibrous loam, and well-dried cow manure on a well-drained bottom, with plenty of water at the foot when growing; blooming, as it does, in the winter, makes this doubly valuable. A very fine variety of this plant, with brighter-coloured flowers, and with more white on the upper sepal, is called *Maulei*. A good figure of this variety will be found in "Floro des Serres," xv., 1561: As an Orchid for room or window-culture in a Wardian case, this has no equal, as it is perfectly safe if preserved from actual frost, although the nearer the winter temperature is kept at 40° Fahr. the better. It should never be allowed to become thoroughly dry at the root, though less moisture is desirable during dull or cold weather, or the plant may suffer from damp. In the "Gardeners' Chronicle," 1842, p. 253, a correspondent recommends this as a drawing-room decorative plant when in flower, and says:—"On the 1st of December I placed eight plants in the drawing-room; there they revelled in the greatest luxuriance for three successive months and, when taken out in March, were as fresh and vigorous as the day they were put in."—Wall. Hook. Ex. Fl. 34; Lodd. Cabb. 1321; Bot. Mag., 62, 3412. The figure under this name in *Bl. Kump.*, 195, is the *C. grandiflorum* of the same author.—*C. insigne* Veitchianum is a still finer variety than *C. Maulei*, the upper sepal being large and white nearly to the base, profusely blotched with crimson. A plant of this was sold in the Meadowbank collection for over twenty guineas.

Shaggy Lady's Slipper (*C. villosum*).—One of the finest and most luxuriant of all the species, which grows equally well either in a hot stove or in a cool Orchid-house. Coming from the hot climate of Moulmein one would expect a high temperature was essential to its well-being, but such is not the case—indeed, the plants seem fresher and more vigorous when grown in a cool, moist, airy temperature than when coddled up in the East Indian-house. The foliage is of a fresh green colour, the base behind being profusely speckled with purple; flowers, solitary, on stout, hairy scapes, 2 in. to 6 in. in height; sepals, oblong, greenish, shaded and streaked with brown towards the base; the spatulate petals are of a bright brown tint, shining as if varnished; the lip is of a pale yellow tint, shaded with purplish-brown, and shining like the petals; the oblong staminoide is honey-coloured, slightly tinged with green, having a blunt tooth or a projecting tubercle in the centre; well-grown specimens bear twenty to thirty flowers, and last six weeks in perfection. This is one of the best species an amateur can add to his collection, as it seldom fails to please. A native of India-Moulmein, where it was found by Mr. T. Lobb, one of the most successful of the Veitchian collectors, at an elevation of 5000 feet.

Hairy Lady's Slipper (*C. hirsutissimum*).—A free-growing plant, bearing large fully-expanded flowers on scapes shorter than the leaves. Although not particularly showy it deserves culture as a variety, especially as it blooms freely at the dull season of the year, when flowers of any kind are valuable; flowers, solitary, the sepals being green, shaded with dull brown, the petals having undulated margins, and a partial twist near their apices, green at the base, profusely dotted with brown, and of a bright purple tint at the apex; lip, green, very profusely dotted with brown. This species was first published by Hooker in the "Botanical Magazine," from Lindley's manuscripts, and the plant first flowered in English collections about 1858. Lindley remarks that it is allied to *C. insigne*, *villosum*, *Lowii*, and *barbatum*, which species he thus distinguishes from each other:—"C. *insigne* is only tomentose, and its petals want the spatulate form, long hairs, and strong undulation. C. *villosum* has longer flowers, no undulation or beard, or ciliation of the petals, and has the sterile stamen truncate, not quadrate. Of C. *Lowii*, the long, flat, naked petals are quite different. C. *barbatum* has a circular, not quadrate, sterile stamen, spotted short leaves, and wants the shaginess. In C. *purpuratum* the sterile stamen is lunate." The plant is a native of Assam.

Mr. Fairie's Lady's Slipper (*C. Fairieanum*).—One of the rarest and most distinct plants in the group, easily recognised when in bloom by the rich purple markings on its dorsal sepal, and by the rich double curve assumed by the petals. The plant is rather small in habit, having pale, greenish leaves that spread horizontally over the top of the shallow pan in which it should be grown. It is rather delicate, and likes a warm, partially shaded position in the East Indian-house or plant stove, with a fresh, open, sandy compost thoroughly well drained. The flowers are solitary on slender scapes, the upper sepal being large in proportion to the other segments, the margins being undulate or plicate or ciliate, while at the apex striped with rich purple or claret markings. The lower sepal is greenish-white and much smaller; petals, curved downwards, green striped with purple, margined with purple hairs. The plant was first described

by Lindley from a specimen which first bloomed with Mr. Fairie, of Liverpool, in 1857. The plant was first imported from Assam, and, although many consignments have been received, it continues very rare. It blooms in the autumn and lasts well.

Mr. Hugh Low's Lady's Slipper (*C. Lowii*).—This is a strong-growing vigorous-habited species, introduced in 1846, and was described soon after from a specimen which bloomed in the collection of A. Kenrich, Esq., of West Bromwich. It is a native of Borneo, where it is found growing on the branches of some of the highest forest trees. I have seen some finely-grown plants in the garden of Provost Russel, of Mayfield, near Falkirk, N.B., who has one of the best and most complete collections of these curious and beautiful plants that I have ever seen. One of these plants bore six flowers on a fine scape nearly 4 ft. long. The foliage is about 12 in. to 14 in. long, and 1½ in. in width, of a dark green colour, the erect scape being usually 2 ft. high and three to four flowered. The upper sepal is downy at the back and pale green within. The petals are 3 in. to 4 in. long, projected nearly horizontally at right angles with the lip. These are spatulate in form, yellowish-green at the base, heavily spotted or blotched with purple, the apices being of a dullish purple tint; the lip is oblong, blunt at the apex, of a shining purplish-brown colour; the staminoide is curiously three-lobed below. This plant, although a native of one of the hottest and most universally humid districts in the world, grows perfectly well in a moderately cool Cattleya-house. They grow best in a fresh open turfy compost surfaced with living Sphagnum Moss, into which its thick hairy roots branch in all directions. This plant is more rarely known as *C. cruciforme*. It is a native of Borneo.

Schlimg's Lady's Slipper (*C. Schlimii*).—This is a charming little plant when well grown, yet growers, as a rule, fail in its cultivation. I have only seen two plants in a first-class condition, one in Provost Russel's well-known collection at Falkirk, and the other in Mr. Edwin Wrigley's garden at Bury, Lancashire. The last-mentioned specimen had leaves 12 in. to 15 in. in length and nearly 2 in. broad, being of a fresh light green colour, and in the most vigorous health. It was growing with *Odontoglossum*, *Disas*, and *Oncidium macranthum*, in a cool moist house, and was literally reveling in a fresh open compost of turfy loam and fibrous peat, surfaced with living Sphagnum Moss. It bears pretty little flowers 1 in. to 2 in. across, on erect, simple, or more rarely branched, spikes. The sepals are oblong, slightly downy, and greenish-white; petals, oval or oblong, pure white, sometimes sparingly spotted with bright purple; lip, rounded, white, suffused with bright rose. The flowers are not unlike those of the North American *C. spectabile* in shape and colour, but smaller. It is very liable to the attacks of thrips, which seem especially fond of its fresh succulent young leaves; a cool atmosphere, regular supplies of moisture at the root, together with daily syringings, and a shady position in the house, will do much to prevent their ravages. It is a chaste little species, well worth culture. It is a native of New Grenada, and flowered with Mr. Bull about 1866.

Long-tailed Lady's Slipper (*C. caudatum*).—This is one of the most attractive of Orchids, and, at the same time, one of the greatest curiosities of the vegetable kingdom. The foliage is strap-shaped, 5 in. to 10 in. in length by about 1 in. wide, and of a bright green colour. The spike is two or three flowered, and is a little longer than the leaves. The flowers are large and handsome; sepals, ovate-alternate, the lower one rather larger than the upper one, 3 in. or 4 in. in length, and of a pale yellowish colour, streaked with deep green markings, and sometimes tinged with rose. The lip is large and very much swollen, yellowish outside, heavily suffused with greenish-purple. The colouring is very rich in the best forms. The infected lobes at the base are of ivory whiteness, spotted with rich purple markings. The petals are the most striking parts of the flower, and are remarkable not only for their great length, but for the gradual manner in which they elongate until the maximum length of from 20 in. to 30 in. is attained. When the buds first open these petals are not much longer than the sepals, but they continue to increase in length, for nine or ten days at least, after the flower opens. It would be interesting to know the cause of their rapid growth, while, at the same time, the rest of the flower does not visibly enlarge; it is, however, a peculiarity evinced, more or less, by all the long-petalled *Cypripedes* and by one or two *Brassias*. Another case, nearly similar, is found in the tail or spur of *Angraecum sesquipedale*, which frequently attains the length of from 12 in. to 16 in. It was pointed out by Darwin, in his "Fertilisation of Orchids," that in its native habitat (Madagascar) there probably existed a lepidopterous insect with a proboscis sufficiently long to reach the nectar, which is secreted at the very bottom of the tube or nectary, and suggested that its so doing resulted in the fertilization of the flower. More recently this has been proved to be the case, and a moth has been discovered in the island with a proboscis

of the required length. In the case of the long-tailed Lady's Slipper I have often thought that it might possibly be fertilised in Peru by large ants or other creatures unable to fly, and that the long petals served as ladders up which they can climb to the sexual apparatus. It is one of the best species in the genus, and should be introduced to every collection. *C. caudatum roseum* is a brighter coloured variety, which succeeds well under rather cooler treatment than the normal type. This plant grows well in a cool Orchid-house where the temperature is kept about 40° in winter, and is very effective. *C. caudatum* first flowered in the once celebrated collection of Mrs. Lawrence at Ealing Park, in 1850. Native of the Peruvian Andes.

Mr. Stone's Lady's Slipper (*C. Stoneyi*).—This may be considered as one of the most attractive species in the whole group. It was first imported from Sarawak by Messrs. Hugh Low & Co., and named in honour of Mr. Stone, an enthusiastic cultivator and late gardener to Mr. Day, of Tottenham. It has smooth foliage of a bright green colour, about 1 ft. in length, and $1\frac{1}{2}$ in. to 2 in. in width. The flowers are borne two to four together, on a large curved erect spike, subtended by large bracts. The flowers are large and brightly coloured; sepals, white, faintly tinged with rose, and heavily blotched behind with purple; petals, 5 in. long, and $\frac{1}{2}$ of an in. broad, drooping, slightly twisted, of a faint colour, streaked and blotched with purple; lip, not unlike a Mahomedan slipper in shape, of a bright rosy-lilac colour, with conspicuous carmine-tinted veins. The style is curiously two-branched, and the staminate is surrounded by a hairy border, like the collar of a Polish tunic. A fine variety of this, *C. Stoneyi platyuncum*, differs from the normal form in having flat petals fully $\frac{1}{2}$ in. to $\frac{3}{4}$ in. broad, richly blotched with purple. It is both rare and valuable.

Glossy-leaved Lady's Slipper (*C. lavigatum*).—In habit this is barely distinguishable from *C. Stoneyi*, and the flowering is the same. It is easily distinguished, however, by its smaller flowers, and by the purple markings in front of the ovate dorsal sepal, as well as the scape, ovaries, bracts, and petals of the present plant being profusely covered with purple hairs, while in *C. Stoneyi* they are perfectly smooth. The petals are also much more distinctly twisted, and vary from $\frac{1}{2}$ in. to 6 in. in length, being of a clear yellow colour, streaked and spotted with purple at the base; the lip is yellow, shaded with purple. This beautiful plant was introduced from the Philippine Islands by the late Mr. John Gould Veitch, who discovered it growing on the roots of *Vanda Batemanni*. Like its congener, *C. Stoneyi*, this only succeeds well in a warm genial atmosphere, partially shaded during bright sunshine, with plenty of light during the dull autumn and winter months. Good specimens of both these beautiful plants bear from three to six fine spikes, each bearing three or four flowers.

Ledge-leaved Lady's Slipper (*C. caricinum*).—This is a modest slender-leaved little plant, well worth growing in a mixed collection. Its bright green grassy leaves are produced from a slender rhizome, which creeps over the surface of the mossy compost in all directions. Its flowers are borne on erect spikes, one to three together, and, though not showy, are extremely delicate in their tinting, and the narrow petals are curiously tortile or twisted like a fanciful corkscrew. Sepals and lip of a pale grass-like green hue; petals, greenish, margined with white, and tipped with purplish-brown. It flowered in Messrs. Veitch's Orchid-house in 1865, and is one of Mr. Pearce's discoveries. It grows well in a moderately cool and humid temperature, with copious supplies of moisture at the root. I have seen this plant growing vigorously and flowering most profusely in a cool lean-to Orchid-house, with air on night and day in summer. Treated in this manner, this species and the pretty little *C. Schlimiti* do well; both like to feel the effects of condensed moisture on their fresh foliage during the night. It is a native of Peru and Bolivia, and is sometimes known as *C. Pearcei*, as a compliment to its discoverer.

Blume's Glandular-petaled Lady's Slipper (*C. glanduliferum*).—This is a rare and curious plant, not at present introduced to our collections. It bears large handsome flowers, two or three together on a scape. Petals, 3 in. to 4 in. in length, acute or sharp pointed, and bearing two or three conspicuous hairy glands along their margins; lip, inflated, pink or bright rose-coloured, with a pair of reversed horn-like appendages inside. It agrees with *C. Parishii*, in having long petals set with large hairy glands, but the petals of the last-named have blunt rounded hairy apices, by which it may readily be distinguished. The only figure I have seen is in "Blume's Rumphia," vol. iv., 198, where it is figured under the name of *C. insignis*, which must not be confounded with the well-known *C. insignis* of Wallich. It is also known as *C. glanduliferum*. Native of New Guinea, and probably also of Java.

Rev. C. S. Parish's Cypripede, or the Elephant-crushed Lady's Slipper (*C. Parishii*).—This is a very interesting plant,

with broadly strap-shaped deep green leaves bifid at the tip. The flower-spike is 1 ft. to 2 ft. long, bearing from three to five large long-petaled flowers; the upper sepal is ovate, with unfolded margins, and has a strongly deflexed reel behind; the lower sepal is rather smaller and reflexed; in colour they are pale greenish-yellow. The petals are 4 in. to 6 in. long, with undulated margins near the base, and the segments become distinctly twisted towards the rounded hairy tips. They are greenish-yellow at the base, margined with purple, while the apical portion is deep claret-purple, with pale margins; each petal has about three hairy marginal glands, the lip is oblong, with the lower lobes inflexed in the usual way, the colour being a decided green, shaded with brown. It grows well in a warm genial atmosphere, and has recently been exhibited by Mr. B. S. Williams, at South Kensington. The only other Lady's Slipper that has the peculiar large hairy glands on its long petals is the *C. glanduliferum*, of New Guinea, and that has not the curious blunt tips to its petals like our plant. The plant was introduced by the Rev. C. S. Parish, who met with it in India, near the Siamese frontier.

Long-leaved or Reichenbach's Lady's Slipper (*C. longifolium*).—This is a free-growing species, introduced by M. Roezli, one of the most intrepid and successful of modern collectors. According to Reichenbach, this plant, *C. Roezlii*, *C. caudatum*, *C. Pearcei*, *C. Schlimiti*, and one or two others, all South American, belong to *Selenipedium*, a genus characterised by having a three-celled ovary. The foliage of this plant is bright green, strap-shaped, 12 in. to 16 in. long, by 1 in. to $1\frac{1}{2}$ in. broad. The scape varies from 2 ft. to 4 ft. long, bearing ten to twelve or more flowers, which open in gradual succession from below upwards, rarely more than one being open at the same time; in this way a plant often lasts in bloom for a whole year or more. The flowers are of a warm, yellowish-green tint, shaded with brown, each having a large green bract at the base. The drooping or divergent petals are 3 in. to 4 in. long, tapering from the base, where they are half-an-inch broad to the attenuated apices. These are of a brownish-purple colour; the lower sepal is much the largest, a very unusual occurrence in the genus, although well marked in the present species and in *C. Roezlii*. These segments are of a greenish-brown colour, the lip being oblong, olive green in front, and profusely dotted or speckled with red. The rhomboidal or triangular staminate has a conspicuous rim of stiff black hairs along its upper margins. It grows well in a moderate temperature. This is also, though erroneously, known as *Reichenbachii* in some gardens. A native of Costa Rica.

Roezli's Lady's Slipper (*C. Roezlii*).—This is a very robust plant, very nearly related to the long-leaved Cypripede, but distinguishable by its much longer and broader foliage, and by its flowers being larger and much more showy. The leaves vary from 12 in. to 18 in. in length, being nearly 2 in. wide, and of the freshest green colour imaginable. It grows freely treated like its congeners. The spike, like that of the last-named, is from 2 ft. to 4 ft. long, with great Strelitzia-like bracts at the base of each flower. The flowers open in gradual succession, rarely more than two being open at the same time, and the plant continues flowering for ten or even twelve months from the same spike. The sepals are ovate, and of a soft rosy tint, the lower segment being nearly twice the size of the upper. The petals are 3 in. to 4 in. long, and of a bright rosy-purple colour; the lip is green shaded with purplish-brown, the inflexed sides being pale yellow, profusely warted, and having two green glands on each side about the centre. It is a noble plant that should be included in every collection. Uplands in South America.

Linden's Uropede (*Uropedium Lindenii*).—This curious and extremely rare plant was named by the late Dr. J. Lindley, one of the most distinguished and acute of all orchidologists. It grows well in a cool house, and was introduced to our collections in 1848 by M. Linden, after whom it is named. As a genus this differs from *Cypripedium* of Linnæus or *Selenipedium* of Reichenbach by having an elongated petaloid appendage in place of the swollen slipper-shaped lip. In habit and mode of flowering the plant is identical with *C. caudatum*, and the flowers closely resemble those of the last-named plant in every respect, except in the slipper being transformed into a long caudal appendage. It does well treated like *C. caudatum*. The plant flowers in the spring, and may be regarded as a monstrous form of the last-named species. It is a native of New Granada, where it grows sparingly in moist woods at an altitude of from 7000 ft. to 8500 ft., and where the mean annual temperature is only 56°. It first flowered with M. Pescatore, of St. Cloud, near Paris, in 1853.

Hartweg's Lady's Slipper (*C. Hartwegii*).—Hitherto this fine species has been known only through dried specimens and the figure in Reichenbach's "*Xenia Orchidaceæ*," but a recent collection of

Orchids sent to this country by Mr. Wallis is supposed to contain this plant, and, if so, it is the first consignment of living specimens of it hitherto received in England. In habit it comes near *C. Roezlii*, having long, arching, bright green leaves, and tall nine and ten-flowered scapes, each flower being produced from the axil of a large Heliconia-like bract. The flowers are greenish suffused with brown, the large, inflated, apple-green lip being streaked with purple. It is a plant of a bold and striking character, and well worth culture.

Drury's Lady's Slipper (*C. Druryi*).—This is a comparatively modern introduction, having been brought from the Continent to this country in the spring of the present year. It is distinct as a species but comparatively unattractive. In general habit it closely resembles *C. villosum*, the flowers being borne singly on rather short, stout, hairy scapes. The sepals and petals are very short and of an apple-green colour, each having a purplish, hairy band down the centre. The lip is greenish suffused with brown. We have only seen this plant in Messrs. Veitch & Son's collection at Chelsea, where it flowered freely a few weeks ago.

Hybrids.

M. Seden's Lady's Slipper (*C. Sedenii*).—This is a very beautiful hybrid, and very vivid in its colouring. It was raised by Mr. Seden, one of the foremen in the Royal Exotic Nursery at Chelsea, and is the result of a cross between *C. Schlumii* and *C. longifolium*. It is an interesting fact that the plants were inter-crossed with each other, and seedlings raised from both; the species, as seed-bearing parents, gave exactly the same results. The foliage is strap-shaped, gracefully curved, and of a bright green colour. Flower-spikes purple, hairy, bearing five to seven flowers each, only one or two being fully expanded at the same time. The sepals are oblong, of a bright rosy colour. Petals oblong, inclined to be strap-shaped, and partially twisted near the apex, creamy-white with deep, rosy margins; lip oblong, bluntly pointed, the mouth being curiously lobed on each side, and having rounded bosses on the front margin. The inflected sides are pure white, dotted with rose, the staminode being slightly downy and tinted with pale yellow. It flowers very freely throughout the winter, and its bright foliage and brilliant flowers make it a general favourite. Grows well in a cool house.

Dr. Harris's Lady's Slipper (*C. Harrissianum*).—This is a very robust, free-growing hybrid, raised by Mr. Dorniny between *C. villosum* and *C. barbatum*. The leaves are 5 in. to 7 in. long, nearly 2 in. broad, and are of a bright green colour, marked with darker green in the way of *C. barbatum*; flowers large, shining as if varnished, shaped something like those of the first-named parent, but darker in colour; the lip is rich purple, the petals being shaded with purple and brown. It grows and blooms nearly all the year round, and is one of the finest plants in the whole group. Some forms are deeper and brighter in colour, but all are good, and well worth culture in the most select collection.

Standard Lady's Slipper (*C. vexillarum*).—This is another beautiful plant raised at Messrs. Veitch's establishment at Chelsea. It has variegated foliage, and is the result of a cross between *C. barbatum* and the pretty little *C. Fairieanum*. The result is a very interesting hybrid, nearly exactly intermediate in character between the two species. The dorsal sepal is roundish-oblong, with undulate hairy margins, of a light greenish tint veined with purple; petals curved like those of the last-named plant, hairy along the margins, pale green in colour, with dark veins and purple spots and markings; lip purple, shaded with green. It flowers during the winter months, and is well deserving of general culture.

Mr. Dorniny's Lady's Slipper (*C. Dorninii*).—This is a free-growing plant with the general habit of *C. caudatum*, except that the leaves are narrower and more gracefully curved. It is the produce of seed from the last-named plant, fertilized with *C. caricinum*, and the flowers, although closely resembling *C. caudatum* in form and size, show traces of both parents; the sepals are light green shaded with dark green, the drooping twisted petals being of a pale yellow tint, streaked with bright reddish crimson; the inflected lobes of the lip are pure white with rich claret-coloured dots, while the sac-shaped central lobe is green, barely shaded with a purplish-brown. It is a most desirable plant, blooming during the winter and spring months, and lasting a long time in beauty if the flowers be kept dry.

Lady Ashburton's Lady's Slipper (*C. Ashburtoniae*).—This is the result of a cross between *C. insigne* and *C. barbatum*. In habit and inflorescence it somewhat resembles both parents. The leaves are shaped like those of *C. insigne*, but are a little broader, bifold at the tip, and covered with dark net-like markings of dark green on a lighter ground. Some individuals are marked nearly as distinctly as *C. barbatum*, while in others the markings are barely

visible. The flowers are in shape similar to those of the last-named, and are borne singly on a slender chocolate-coloured scape about a foot high. Upper sepal white at the apex, greenish at the base, having numerous deep brownish-purple stripes, and blotches; petals slightly deflexed, oblong, wavy along their margins, of a greenish-white with deep purplish veins; the margins being hairy and tinged with purplish-rose. Lip oblong, rather blunt at the point, and narrowing towards the mouth; the colour is greenish shaded with purple, the depth of colour varying in different individuals. It is an interesting and easily-grown plant, well worth growing. It was raised by Mr. Cross, late gardener to Lady Ashburton, at Melchet Park, Hampshire, after whom it is named.

Mr. Cross's Lady's Slipper (*C. Crossianum*).—This is another pleasing hybrid, raised at the same time as the last, and from the same parents. Its oblong foliage is intermediate between that of *C. insigne* and *C. venustum*, being of a glaucous green tint above, paler below, blotched with purplish-black towards the base. There are a few dark reticulations on the upper surface of the leaf. The flowers are borne on purple hairy scapes, 8 in. to 12 in. in length, the bracts being glaucous with purple spots; upper sepals white at the apex, pale green below, with dark green nerves, and a few purple spots at the base; petals strap-shaped, slightly wavy, of a brownish-copper colour, with dark purple or blackish spots; the lip is yellowish shaded with bronze, and having the green net-work as in *C. venustum*; the staminode is like *C. venustum* in form, but of a yellow or pale honey colour, as in *C. insigne*. It is an interesting plant, and must not be confounded with *C. barbatum* *Crossii*.

C. canatum.—A distinct and singular seedling, raised in the Exotic Nursery, Chelsea, where it first bloomed in the spring of the present year. It is a seedling from *C. Harrissianum* (*C. barbato villosum*), itself a hybrid, and the pollen parent is supposed to have been either *C. Stonei* or *C. insigne* *Manlii*. In general habit and colour it resembles the female parent, but there is much white at the tip of the dorsal sepal and some spots which suggest *C. insigne* *Manlii*, while the purple-striped ovary is exactly like that of *C. Stonei*, except that it is densely hirsute. It is a good addition to robust stove Lady's Slippers, and well deserves culture.

C. pycnopterum.—This plant somewhat resembles *C. hirsutissimum* in general habit, but bears a two-flowered scape, at least it did so on its first blooming in the Exotic Nursery at Chelsea, where I saw it a month or two ago under the care of Mr. Seden. In colour and markings the flowers resemble those of *C. Lowii*, but are scarcely so large. The texture of the leaf exhibits that glistening layer of surface-cells so characteristic of *C. venustum* and its forms that I am inclined to think that that species and *C. Lowii* must have been the parents of the hybrid in question, although no records have been kept of the cross. It is very distinct, and well deserves a place in collections. F. W. B.

The Gardener's Life.—"Thus we associate gardens and orchards with the perfect condition of mankind. Gardeners ourselves by birthright, we also mythologize and plant our Edens in the midst of us, like our ancestors; the sacredness of earth and heaven still clinging to the tiller of the ground. Him we esteem the pattern man, the most favoured of any. His labours have a charming innocence. They yield the gains of a self-respect denied to other callings. His is an occupation friendly to every virtue; the freest of any from covetousness and debasing cares. It is full of honest profits, manly labours, and brings and administers all necessities; gives the largest leisure for study and recreation, while it answers most tenderly the hospitalities of friendship and the claims of home. The delight of children, the pastime of women, the privilege of the poor man as it is the ornament of the gentleman, the praise of the scholar, the security of the citizen, it places man in his truest relations to the world in which he lives. And he who is insensible to these pleasures, must lack some chord in the harp of humanity, worshipping, if he worship, at some strange shrine. Who lives a garden still his Eden keeps; perennial pleasures plants, and wholesome harvest reaps."—ALCOTT—TABLETS.

The Old Days of Price's Patent Candle Company.—Mr. G. F. Wilson, late manager of Price's Patent Candle Company, has just published an interesting account of the rise and progress of that establishment, for the conversion of Palm and Cocoa-nut oils into candles. In the appendix are given several items of valuable information relating to the production of Chea butter and Palm oil; from which it would appear that the land on the banks of the Niger and Chadda are much more highly cultivated than is generally supposed. We observe that Mr. Wilson casually remarks that ten years hence for one beautiful hardy plant now common in our gardens, we shall have ten.

THE INDOOR GARDEN.

THE PEARLY ALOE.

(HAWORTHIA SUBULATA).

ONE of the most ornamental of the large tribe of Aloes, numbering some 200 distinct species, is the *Haworthia subulata*, generally called Aloe margaritifera, or Pearly Aloe, of which the annexed is a representation. It has a very short stem, and leaves which are flat above and convex below—in short, triangular in shape and rounded towards the tip. They are covered with a number of white, horny tubercles, which resemble pearls, and give the name to the species. The flowers are greenish, with whitish lobes marked with a green line, and are grouped together in a terminal spike. The beauty of this Aloe, or *Haworthia*, however, resides in the leaves, the flowers being, comparatively speaking, insignificant. It is by no means difficult to grow, nor are any of the genus to which it belongs; the best soil for it is a mixture of three parts loam and equal parts of leaf-mould and sand, and it likes good drainage and partial shade in a cool greenhouse. J. C.

of this beautiful plant is at the present time unequalled. Those who remember the International Exhibition of 1866, will not soon forget the beautiful bank of flowers Mr. James then staged, which seemed to have reached the highest possible degree of perfection. The plodding florist, however, never sits down to "rest and be thankful:" for, if unable to do much for improvement in the way of hybridisation, the simple process of selection and constant increase from the finest flowers is always at his disposal. It is this kind of treatment of *Calceolarias* of which Mr. James is continually availing himself for the production of next season's flowers, invariably

selecting from the plants that have a stout, erect, but compact habit of growth, and from flowers that have, in addition to striking hues or beautiful markings, a bold, full form, good size, and devoid of what is termed "bagginess," a grave defect, and too common in many plants. A good strain of the herbaceous *Calceolaria* produces immense trusses of bloom, the individual flowers of which, although thickly clustered, are yet large, rounded and full, having no lobes or indentations, but each perfect and exactly in its place. Many of these trusses when fully expanded measure 6 in. across, and when seven or eight of these are produced on one plant a grand specimen is obtained. Not the least remarkable fact in connection with the herbaceous *Calceolaria* is the rapidity with which fine exhibition plants are obtained from seed. Mr. James does not sow the seed until about the second week in July, but in ten months he is enabled to show grand plants raised from that sowing, about 15 in. in height and 18 in. in diameter, that are a mass of rich bloom and fine vigorous foliage—perfect marvels of

The Pearly Aloe.

CALCEOLARIAS.

THE herbaceous *Calceolaria* is one of the most beautiful of greenhouse flowers, and perhaps less frequently met with than it deserves, which fact rather indicates a difficulty of cultivation than a defect in the plant itself. Its annual character prevents the establishment of named kinds; and to many persons this should prove a recommendation, for a packet of seed of a good strain, like the *Primula*, gives, in the course of a few months, a superb display of bloom, without the trouble incidental to the propagation and correct naming of catalogue kinds. The *Calceolaria* is eminently a cool plant, abhorring heat, and, as a necessary consequence, the attendant danger of insect life; indeed, the difficulty of keeping the plants free from blight, and in a state of clean, healthy vigour, is the rock on which so many growers of the *Calceolaria* have foundered. Another great risk of failure is to be traced to the too common practice of sowing early, and thus getting the plants stunted by the summer-heat, instead of growing them rapidly direct from the seed-pan, and not allowing them any rest until in full bloom. The most successful cultivator of the herbaceous *Calceolaria*, probably, is Mr. James, of Redlees, Isleworth, and his celebrated strain

cultivation. The seed is sown in shallow pans and in fine sweet loam, with which there is a good admixture of sharp silver sand; the pans are placed on a shelf in a cool house, and kept shaded from the sun. The seed speedily germinates, and the plants grow so rapidly, that they are soon large enough to be pricked out into other shallow pans, which are again placed on a shelf and shaded as before, or placed in a cool frame close to the glass. In a short time the seedlings are ready to be potted up into large 60-sized pots, and are again placed in a cool frame for a few weeks, care being taken that none are allowed to get dry at the roots,

and sufficient air given to keep the foliage clean and vigorous. Ere the pots are full of roots, another shift should be given, this time either into 32 or 24-sized pots, according to the size of the plants, and if extra fine specimens be desired, the largest should have a final shift into 16-sized pots, in which they will develop into grand plants. Insects must be constantly looked for, and if found troublesome, the plants should have an occasional dip into weak Tobacco-water; but under ordinary circumstances an occasional fumigating should keep them free from these pests. The flowers, of a fine strain, are remarkably varied, and range from creamy white to intense maroon-crimson—the Redlees plants being prominently marked with very dark rich hues. The blotched forms are most interesting and beautiful, and are commonly found on primrose, yellow, and orange grounds; indeed, taken altogether, the Calceolaria has few rivals as a decorative plant at this time of the year.

A. D.

Fuchsia Sunray.—This is among Fuchsias what Mrs. Pollock was among Geraniums when it first came out. I have included it among my stock plants. It is a free-growing, neat-habited Fuchsia, furnishing well as it grows, and naturally forming a pyramid if not pushed too much in strong heat. The leaves are broad, regularly and distinctly splashed with creamy-white and green, suffused with crimson, especially at the points of the young shoots, a circumstance which gives the plant a distinct and highly ornamental appearance. The variegation is constant, and the different shades are more distinctly produced when the plant is grown in the greenhouse, and well exposed to the light, than elsewhere. Generous treatment and a good soil increase the size of the leaves without affecting the variegation, and, as the flowers are unimportant, it is best to pick them off, as they only weaken the shoots. Cuttings of this variety strike freely in the usual way, and should be potted off singly; small plants, about a foot high, look best, and are most useful.—C.

Violets in Pots.—The possession of such varieties of Violets as the Czar and the new Victoria Regina gives quite a new aspect to the culture of Violets in pots. The old Neapolitan, though likely to hold its own against all comers, as regards sweetness and free-flowering habit, was hardly adapted for pot culture; it thrives in a bed of good soil in a frame, but in pots it is apt to become somewhat shabby, being subject to red spider, and a weak grower, a great drawback to pot plants of any kind. With the varieties of the Czar type it is, however, different; they have robust, bold, and erect foliage, which fills and looks well in a pot, and they are sure bloomers, and throw their flowers up well above the leaves, stand forcing better, and bloom in great profusion. I have just lifted a quantity of last year's roots of the Czar and Victoria Regina, sub-divided them, using both the old crowns split up and rooted runners, and potted them in 5-in. pots in good, light, rich soil, and hope to have them in flower early in the winter without much forcing. I used to content myself with lifting the roots out of the ground and forcing them at once; but, like Strawberry plants, prepared ones succeed best. The plants should be plunged in ashes during the summer, or, at least set thickly together—to keep each other's roots cool—in a rather shady situation. They should never be exposed to the full force of the mid-day sun, and should at all times receive plenty of water at the roots. Before the weather becomes so severe in autumn as to injure the foliage, the plants should be moved into a cool frame (fire-heat will hardly be needed), and from such quarters they can be introduced into the greenhouse or conservatory as required, when they will continue to produce flowers for a long period if they be properly attended to, and above everything, kept near the light.—CHR.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Soil for Camellias.—I had some top-soil from a pasture, and mixed it with lime and bones, about two years ago. I intend using half of this, and the other half good turfy soil, from a pasture on limestone rocks, for my Camellias. Can this mixture be recommended?—M.—[With the exception of the lime, of which we should use as little as possible, your compost will suit Camellias perfectly.]

Successful Culture of Calochortus.—These beautiful bulbous plants from the Pacific side of America have hitherto been seldom cultivated with success in this country, our cold winters destroying the foliage that passes through a Californian winter and spring without injury. In the Hale Farm Nurseries at Tottenham, they are very well grown planted out in shallow frames, where they enjoy a sufficiently moist and open gritty soil below, besides the advantage of a light, dry soil on the surface of the beds. They get good light, being quite near the glass; they are planted early enough in the autumn to ensure an early growth, and, as a consequence, they flower abundantly.

THE DADDY-LONG-LEGS.

THIS insect is in a general way objectionable, but particularly so at the present time in and near London. A considerable number of Grass plots in places of public resort are just now absolutely destitute of Grass, and present a most deplorable appearance. This is especially the case with the large and useful open space known as London Fields. The new garden in Leicester Square is destitute of Grass; the turf on the Thames Embankment gardens is unusually thin, and, indeed, whichever way we turn we are pretty sure to meet with similar examples. There can be no doubt that the proximate cause of this is the dark grub of the Daddy-long-legs (the Crane Fly, *Tipula oleracea*), which is sufficiently well known to render description unnecessary. This larva has a peculiar taste for Grass-turf; it is partial also to Lettuces, Strawberries, and, indeed, will eat almost any of our kitchen garden vegetables, and has quite a fancy for a feast in a seed-bed, where it will thin the rows of seedling plants with a severity worthy of a better cause. The extent to which the pest has spread in some districts of London is almost past belief. We have seen some spots in London Fields where the ground seems to be so literally alive with this insect that handfuls of it may be taken up with but little searching. It is difficult, at least at present, to say anything useful respecting this daddy-long-legs. But a patch of Grass anywhere in a great city is so precious that we may with propriety ask why the insect should prove so specially destructive amongst houses, while, as soon as we escape from the town we find the turf everywhere in good condition, or if not so, at least not seriously injured by this insect-destroyer. What makes the difference? The answer is obvious—Wherever song birds are fairly plentiful Grass thrives, and where they are scarce daddy-long-legs has it all its own way. It is true that in town sparrows abound, but these rarely hunt for earth grubs, whereas the thrush, the black-bird, and the whole tribe of warblers that dwell with us during the summer season, subsist chiefly on insects, which they pursue from daybreak to dusk. We cannot, of course, compel song birds to locate themselves in towns, but we are bound, in the interest of one of the principal charms of English rural scenery—that is, fresh green turf—to protect them to the utmost of our power, and happily the well-planted suburbs of most of our great towns are plentifully stocked with these delightful and useful birds. It will be found that wherever they abound, the keeping of Grass turf is a comparatively easy matter, but that wherever they happen to be scarce the *Tipula* is a frequent and a powerful enemy. In the spring of 1855 the great parks in the west of London were almost as bare as London Fields and Leicester Square are at this moment, and numbers of remedies were proposed. One of the best of these was that of the late Mr. Cuthill, who recommended rolling the Grass at night with a 2-ton roller, with a Thorn-scrubber behind well loaded. Then followed a host of proposals more or less suitable for adoption on a small scale, but inapplicable to such vast areas as the London Parks. One of these consisted in watering the turf with a mixture of corrosive sublimate dissolved in muriatic acid in the proportion of 1 oz. to half a pint of acid, and the addition of 60 gallons of water. Gas-water, quick-lime, lime-water, salt-and-water, and other cheap preparations that usually prove fatal to insects, are of no special value in this case, because to employ them sufficiently strong to penetrate the leathery jackets of these grubs makes the case worse by killing whatever Grass still remains for the renewal of the turf. The best mode we have as yet heard of for dealing with this plague is contained in a report to the Parks and Open Spaces Committee of the Metropolitan Board by Mr. N. Sinclair. He says, "The experience by which I obtained this method was gained through a similar invasion of the Embankment Gardens by these insects four years ago, when I had the opportunity of studying their habits and ascertaining the best means for their destruction. I found that only certain portions of the gardens were infested, from which I infer that their haunts depend much on the wind and weather, being thus driven to collect in the most sheltered places, where they deposit their eggs. The grubs make their appearance in January, and when commencing their depredations may be captured in thousands by cutting square trenches 6 in. wide and 6 in. deep, into which the grubs in their wanderings fall, and since they cannot crawl up the perpendicular sides of the trench, they may be swept up the next morning and thrown into salt, that being the only substance I have found efficacious in killing them. I have tried other things for that purpose, such as quick-lime, soot, snuff, &c., but none answered the purpose so well. The remainder of the grubs that are not swept up fall to the chrysalis state, and in due time come forth as the well-known daddy-long-legs, and soon after spread themselves abroad and deposit their eggs wherever it is most likely their offspring will find suitable sustenance. As soon as they make their appearance on the wing there is nothing better than heavy garden rollers. On bringing these into play the extermination of this obnoxious pest may be considered complete.—"Gardeners' Magazine."

LAMPS FOR WARMING CONSERVATORIES, &c.

KEEPING frost out of small greenhouses by means of lamps and candles, as noticed by a correspondent in a recent number of THE GARDEN, is not new; on the contrary, it was frequently practised in the days of tinder boxes and rush-lights. Four of the latter I once saw placed in a row, and lighted at night, whereby the temperature of a conservatory was raised several degrees. What advantage the petroleum lamp-stove has over this rough-and-ready mode of heating it is not very easy to discover. The fallacy underlying that invention may be traced to the ordinary stove and open fireplace, in which the vapour is allowed to escape by means of a chimney. In all modern improvements the aim of the inventor has been to extract as much of the heat as possible from the burning fuel before it has passed up the chimney in the form of smoke. Even in the best constructed grates it is well known that by far the larger half of the heat escapes in that form; but when a lamp burns in a room, the latter receives all the heat—not a small portion of it only. In the chimneyed stove are

Lamp, for warming conservatories, &c., with cylinder and reflector.

found all the appliances by which the heat can be radiated, and in that way abstracted from the burning fuel; and the chimney itself is frequently turned to account as a radiator of heat when it takes the form of a stove-pipe. But where no provision is made for the escape of the products of combustion, the chamber then gets the whole of the heat generated, and there is consequently less need of radiating surfaces. Bright metal would not answer that purpose, but rather tend to confine the heat and make it take an upward direction. A terra-cotta envelope might act as a radiator were that required; but it is the lamp that gives the heat; and all the heat that is generated in a petroleum stove proceeds from the lamp, and from the lamp only. If the products of combustion be let into the room, there is no need of an expensive metal case. It is a law, admitting of no exception, that the same weight of the same fuel will always give, in whatever way it is burnt, whether quickly or slowly, the same amount of heat. If the proceeds be let into the room, all the heat comes into the room, and the twenty shillings' worth of tin or the forty shillings' worth of copper is doing nothing. If it has been found by actual experiment that the lamp, when taken out of

its metal envelope, did not raise the temperature of the room as it did when burnt in it, the reason can only be that it consumed the oil faster; in fact, that it did the work and consumed the oil of a larger lamp, so that no real advantage was gained from its metal case. Another point to be considered in connection with this stove is the notion that it produces a dry heat, and therefore requires an addition in the form of a vaporizer. Now, when it is remembered that from lamps and candles the products of combustion are carbonic acid and water, this arrangement seems almost superfluous. A vaporizer is needed where, as in a common chimneyed stove, the products are allowed to escape in the form of smoke. In winter, when heat-producers are most in request, it is damp, and not dryness with which we usually have to contend; and even a hot fire does not at that season require any great amount of vaporizing. To prevent the waste of heat which usually takes place in the upper portion of a glass structure, there should be suspended immediately over the lamp a metal reflector, as noticed by your correspondent. The form I recommend is that of a flattened blossom of a *Convolvulus*. It should be kept bright on the underside to act as a conductor, and cause the warm air as it rises to take a horizontal direction. As the lamp would require some sort of frame to hold it and to protect it from accident, it might stand on a disc of sheet iron 7 in. in diameter, through which three $\frac{1}{2}$ -in. iron wires should pass, and be secured with shouldered and screwed ends to the feet by nuts. The upper ends of these wires should be gathered together and terminate in a ring. A cylinder of tin, 6 in. in diameter and about 12 in. high, perforated at the base with draught holes, and painted outside

Form of Tin to make reflector.

with lamp-black if wanted to serve as a radiator, sliding over the wires and resting on the disc, would complete an inexpensive frame, which any ironmonger could make for a few shillings. Four sheets of tin cut into this form, and riveted or soldered together, would suffice for a reflector. The distances (1) between the point of suspension and the reflector, (2) between the reflector and the lamp, (3) between the lamp and the ground would have to be determined by experiment, care, however, being taken that the reflector should be at such a distance from the lamp that it does not acquire a temperature of more than 100° Fahr. The lamp, if used without a reflector, should be placed low, and might even stand upon the ground. The $\frac{1}{2}$ -in. wires should extend about 12 in. above the top of the cylinder, and the latter would have simply to be raised whenever the lamp was put in or removed.

B. S.

New Buildings at Kew Gardens.—We learn from the "Builder" that under the superintendence of Her Majesty's Office of Works some new buildings and extensions are about to be made at the Royal Botanical Gardens at Kew, for the reception of specimens of plants and flowers, and that for this purpose the west wing of the Herbarium, adjoining the entrance to the gardens, is about to be demolished.

Cheap Cisterns.—It is not generally known, according to "Moore's Rural," that cisterns can be made without either brick or stone, wherever the earth is sufficiently compact to admit of digging out the soil and leaving a firm bank upon which cement can be spread to a thickness of 1 in. or 2 in. The cement soon hardens, making a wall as tough as a stone-jog. The top may be covered with plank, with timber support, and then covered over with about 2 ft. of earth to keep out frost. Of course a man-hole, through which the cistern can be entered for cleaning, is also necessary.

Plant Specific against Hydrophobia.—Dr. Grzyzala, of Krivoe Ozero, Podolia, has found that after having treated at least a hundred cases of men bitten by rabid dogs with *Xanthium spinosum*, he has never in any case failed to ward off hydrophobia. For an adult, the dose is sixty centigrammes of the dry powder, repeated three times a day, and continued during six weeks. Children under twelve take half that quantity. The dose for animals is much larger.

Latin Names of Varieties.—Our readers may remember that when Messrs. Maxwell and Barry introduced two varieties of Arbor-vitæ, and named one George Peabody and the other Tom Thumb, and we supported them in the excellent innovation, the English nurserymen refused to know these varieties under these names, and re-christened them with Latin names of great length. We cannot see how Latin names are to be obviated so far as species go, but for varieties they are needless and absurd. Here before us is a list of garden forms of Holly. One is *Ilex Aquifolium aurea angustifolia marginata*, another *Ilex Aquifolium serratifolia alba marginata*, and so on. Even in Europe as in this country there have been attempts at rebellion. Mr. Waterer named one Holly Golden Milkmaid, but he seems to have been subdued, and the kind is declared to be *Ilex Aquifolium aurea medio picta*—only this and nothing more!—T. MERRILL, in "Gardener's Monthly."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Flower Garden.—Now is a good time to put out all the remaining tender bedding plants, such as Coleuses, Alternantheras, Iresines, and others of similar character. They will be found to have been much better indoors than out. By the end of the month the later put out plants will, in all probability, have considerably outgrown those that were planted whilst the nights were colder.

Kitchen Garden.—Where the ground has not been previously well prepared it is difficult to deal with it after the crops are in and growing, nor will all kinds of vegetables bear treating in one uniform way, as the deep stirring of the soil between the rows, that will be of the greatest benefit to such plants as push their roots mostly downwards, would be very injurious to surface-rooting plants like Cabbages that had already occupied the soil to a considerable extent. Where the soil is in a hard impervious condition, such as it has been in many places this year, the hoe will be all but useless, and will have to give way to the fork; this should be used freely, digging the ground to a good depth in all cases, without disturbing those roots that have made some progress in entering the soil. Parsnips, Carrots, Beet, Potatoes, Turnips, Peas, and Beans of all kinds will be much benefited by the ground being thoroughly loosened up and left with the surface in a comparative rough state until sufficiently acted upon by the drying influence of sun and air, after which, when enough rain comes to moisten it again, the whole will crumble down freely when the hoe can be used afterwards as required. Spring-planted Cabbages, Cauliflower, and Lettuce should have the surface for a few inches forked over, in all cases going as deep as the roots will permit. After all is done that is possible, crops that were put in the ground whilst it was in such an unusual state as it has been this season can never be expected to do so well as when sowing and planting has been carried out under more favourable conditions; but a thorough loosening up of the soil, such as described, will do a good deal to assist the later crops. Where amateurs, whose gardens are composed of heavy adhesive soil, have followed the advice I have previously given of using a few inch boards, 8 ft. or 10 ft. long, and 1 ft. wide, for laying on the ground when sowing and planting, so as not to necessitate placing a foot upon the soil after it is dug—the advantage of this will be readily seen, as it is the treading and unnecessary raking that so much aggravates the evil. The use of such boards causes very little delay, as one edge answers in the place of a line by which to plant a row or draw a drill for seeds. In the case of amateurs, whose gardens are generally of moderate extent, where the soil is of a heavy nature and difficult to work in spring, much might be done by incorporating with it the ashes produced in the household; if this material were passed through a fine riddle, about a quarter-inch mesh, regularly spread upon the surface and dug in, its effects would be soon apparent in the much more workable condition of the ground after wet weather. In districts where either river or pit sand can be had for carting this is even preferable to ashes, and may be applied from 4 in. to 6 in. in thickness. Any heavy land that has yet to be cropped and that was dug some time back before it had time to dry, should, in all cases before being sown or planted, be again dug over, bestowing more than the usual amount of labour on it in reducing the hard lumps. Every attention needful should be given to the later crops; if, as often occurs after an ungenial spring, we have a protracted autumn, the produce of the later sowings and plantings may in some measure make up for disappointments as regards the earlier ones.

Peas.—More Peas should now be sown, giving them the most open position that can be selected for them, as upon this to a considerable extent depends their escaping mildew, which is so fatal to autumn Peas in many localities, especially where the soil is light and the sub-soil dry; where such conditions exist it will be well to make some provision to counteract its effects, otherwise it is of little use going to the trouble of sowing for a late crop. Trenches should be opened about 18 in. wide and from 18 in. to 20 in. deep, *i.e.*, if there be sufficient depth of soil; in the bottom put 8 in. of a mixture, half manure (cow or pig is preferable) and either marl or clay well pulverized; on this put as much of the soil that was taken out as will fill up the trench to within 4 in. of the top; after it has been slightly trodden down to solidify it, sow Peas of any approved large kind. The White Marrows are not usually so much subject to the attacks of mildew as the green, of which *Ne Plus Ultra* may be taken as the representative. Another matter of equal importance to preparing the soil, with the view to avoid mildew in these late Peas, is to give them plenty of room, both in the rows and between them; allow 6 ft. between the rows, and if in a trench like that described a couple of rows of the Peas be put 4 in. apart, it will be thick enough; in covering the seed, leave the surface of the trench an inch or so lower than the surrounding

ground, so as to admit of the rows being thoroughly soaked with water in dry weather, especially when the pods are swelling off, as any deficiency of moisture at the roots about this time will favour the appearance of the parasite. Advancing crops of Peas should have sticks placed to them as these are required, never deferring this until they get so high as to be blown about by the wind. Sticking a row of Peas may appear a simple operation, but there is not one man in a dozen, even amongst those who are accustomed to it, who does it properly; the way in which it is generally carried out is to put the longest sticks in, so that their points meet together, forming a close narrow ridge at the top, and allowing the Peas to escape before they get even half way up; stuck in this manner their tops get broken by the wind, whereas if the sticks were placed upright and as wide at the top as at the bottom, the Peas would be kept inside the sticks, and would thus be free from accident.

Beans, &c.—A few more Runner Beans should now be sown; if these can be placed at the south side of a wooden fence or wall, where they will receive some protection, they will in all probability afford a supply in the autumn, after those in more exposed situations are cut off by frost. Another sowing of dwarf French Beans should also be made, as well as a few more Turnips; it is not advisable to put in much of this vegetable now, only just enough for a successional supply, as they will yet grow too large before winter, and not be so good for keeping as the produce of later sowings. A little Walcheren Broccoli and Veitch's Autumn Giant Cauliflower should be sown immediately, from which, with a favourable autumn, heads may be cut up to the close of the year. A pinch of Colewort seed may now be sown with advantage, as Coleworts are always handy for filling in in spare corners. Those who grow Coleworts should see that they get the right sort, which is very different from the nondescript Cabbage that is often substituted for the true variety; so much is this the case that many cultivators of small gardens have never grown the true kind. More Lettuce should be sown in rows where they are to be grown; if a trench be opened a foot deep, and the same in width, half filled with rotten manure, and mixed with a portion of the soil that has been taken out, the remainder being used to form a slight ridge on each side of the trench so as to hold water, running to seed will be reduced to a minimum, and Lettuce thus grown will attain a size and quality not to be surpassed under any other method of cultivation. Endive, on account of its beautiful appearance, is held by some in high estimation, even when Lettuce is plentiful; where this is the case a little should now be sown, and if the ground be prepared in the same way as recommended for Lettuce, the produce will attain a large size before it shows a disposition to run to seed. When the weather is showery the principal crop of Celery should be planted, giving the plants a good soaking with water previously, so that as much soil as possible may adhere to their roots; by this means they will sustain very little check. Immediately a row is planted give it a thorough watering.

Cauliflowers and Broccoli.—The land for Broccoli should be in good condition, and be careful to give all that are intended to stand the winter abundance of room, for by no other means can the requisite sturdy habit be imparted to the plants to enable them to bear severe weather. Half the losses experienced with Broccoli in sharp winters may be attributed to the plants being weak through the effects of being grown too closely. Cauliflowers do not require nearly so much room; where ground is not over-plentiful, a space of 2 ft. in the rows, with 2 ft. 6 in. between each row, will suffice.

Tomatoes should now be planted against walls, and if the border be poor give them a little well-prepared soil to start with; but they are none the better for having the material in which they are to grow too rich, as it produces rank growth in place of fruitfulness.

Stoves.

Many stove plants will now be getting sufficiently forward to enable them to be gradually hardened off, preparatory to removing them to decorate the conservatory, for which purpose *Allamandas*, *Crotonas*, *Dracaenas*, *Bougainvilleas*, *Clerodendrons*, *Stephanotis*, *Ixoras*, and similar plants are well adapted. The whole of these, if properly prepared by gradually subjecting them to cooler treatment, will remain for several weeks in the conservatory without suffering the least injury, provided they be placed in positions away from draughts, or where air, when admitted, does not have full play upon them. Amongst stove flowering plants, *Allamandas* are perhaps the most valuable, on account of the comparatively low temperature they will endure, and the length of time they last in bloom when removed from stove-heat. All shoots of these now showing flower-buds should be carefully regulated and tied so as to distribute them as equally as possible over the entire surface of the plant, without

Siving it a stiff, formal appearance, which a too rigid training of the young wood is sure to impart. Any that were pruned, and started later, for succession, should be placed where they can have the full benefit of sun and light, without which the growth will become long-jointed, sappy, and produce but little bloom.

Bougainvillea glabra.—This, grown as a pot plant, is highly ornamental, and conforms readily to almost any kind of training, as it may be grown in the loose pyramidal form, or on trellises, after the manner of Stephanotis or others of that class. The former, however, suits its habit best, and shows off its rich mauve-coloured bracts to the greatest advantage; but to get them in this shape they must be grown from the first, much in the same way as a well-managed *Fuchsia*, in order that they may be thoroughly furnished with side branches. Before starting them into growth, these should be pruned back to a single bud, and those that are misplaced or superfluous should be thinned out, to allow plenty of room for the new growth. If placed where they can have plenty of light and full exposure to the sun, they make firm, short-jointed shoots from 1 ft. to 2 ft. long, laden with bloom. When in this condition, few plants are more valuable or effective for exhibition purposes or conservatory decoration, where, if properly hardened before being placed in a cool temperature, they will last at least two months in good condition, and their leaf-bracts will come much brighter coloured than if subjected to a closer and warmer atmosphere. *Bougainvillea glabra* flowers freely in a small state, and cuttings put in now will, if grown freely on during the summer, make useful plants for next season. Any of these that are planted out, or in large pots where they are making much growth, should have the weakest shoots thinned out, that the necessary light and air may be admitted to the others to induce plenty of bloom. As a pillar or roof plant in warm conservatories, it is most valuable, provided it can be planted in a light sunny position. *B. speciosa* will likewise stand in a house that does not go below 55°, if its roots can be accommodated with a little dry heat by having the plants near the boiler or pipes; and when that is the case it is the grandest plant that can possibly be introduced. The flowering of this successfully depends entirely on the thorough maturation of the wood now forming, and to give this every chance of becoming properly ripened, the plants must be kept freely thinned out during the summer, that every shoot may be fully exposed to the influence of sun and air. To check the exuberant growth these plants invariably make unless their roots are confined to a very limited space, they should only be afforded sufficient water to keep them from flagging severely, a course of treatment that has a very beneficial effect on them.

Gardenias.—To get these to flower freely next winter every encouragement must now be given in order to induce them to make free, vigorous growth. This may be accomplished by plenty of heat and atmospheric moisture, caused by shutting up early and syringing heavily whenever the weather favours such a course. A deep pit, where they can remain on a bed of fermenting material, will be found the best place for them for some time to come, as they delight in the genial moisture constantly arising therefrom. Any that have been cut back and are now making fresh shoots should have the earth surrounding the roots slightly reduced, and be re-potted in rough, fibry peat, after which they must be kept close and shaded for a time till they get hold of a new soil. Young spring-struck plants will require shifting from time to time as they fill their pots with roots, that they may be got to a useful flowering size as quickly as possible. Gardenias are very subject to both scale and mealy bug, and will therefore require close watching to keep them free from such pests.

Winter-blooming Plants, such as *Euphorbia jacquiniiflora*, *Poinsettia*, *Justicia flavicoma*, *Thyracanthus rutilans*, and others of that class should now receive every encouragement to induce a free growth, and to enable them to attain a useful flowering size by the autumn. The first of these may still be propagated if a deficiency of stock be anticipated, as there is yet time to get plants of these struck and grown to a sufficient size to produce fine heads of bloom for cutting. When they are much in request for this purpose, a few planted out in a light airy position, tolerably close to the glass, to give them colour and substance, will be found of great use, as they branch off into numerous shoots that are sure to flower freely from being so well ripened. Many experience a difficulty in getting *Euphorbia jacquiniiflora* to root freely, and this is sure to be the case if the cuttings be not taken off with a heel, or be allowed to become too long before being planted. If taken off when they are about 4 in. long, with a thin slice of the old stem attached, they will be found to root readily if placed in a close propagating box, or where conditions are otherwise favourable. *Poinsettias* root freely if treated in the same way, and cuttings of these should be got in at once; for, if struck after this, the bracts will be small and imperfect.

Any that have been cut back, or others now rooted, should be kept well up to the light, to prevent the young shoots from becoming drawn, which they soon do if not fully exposed, or the plants are grown in too great a degree of heat, with an insufficient supply of air. Plants of this character, and many other soft-wooded, quick-growing stove subjects, can be best treated during the summer months by placing them in pits or low houses away from the general collection, in order that they may be more easily attended to.

Bouvardias.—To bloom these plants successfully, they require special treatment, and beds for their reception should now be prepared for their summer growth. A pit or frame, having a sufficient depth to place a few leaves or other fermenting material, for the purpose of affording a slight bottom-heat, will be found to suit them admirably, or any old half-spent hot-bed may be utilised in the same way. Bouvardias delight in soils that contain a quantity of decomposing vegetable matter, and, therefore, plenty of peat or leaf-soil should be employed to mix with the loam before planting—two-thirds of the former to one third of the latter, with the addition of a little sand, will suit their requirements. This should be placed to the depth of 6 in. or 8 in. on the bed of fermenting material, and the young plants turned out in it at the above distance apart, after which they must be kept moderately close and shaded for a time to give them a start. When they get fairly hold of the soil, plenty of air should be given them, and during favourable weather the lights may be left off altogether. A bed similarly prepared in a warm, sheltered position without bottom-heat will push them forward almost equally well; but in either case they must be properly supplied with water, and kept well syringed during the summer. Planted out and treated in this way, they make much finer plants than they otherwise would if confined to pots without requiring so much labour and attention. To induce a bushy, compact habit, the tips of the strong leading shoots should be nipped out occasionally if they appear to be taking the lead; but this should not be done after the middle of August, as all that form after that time should be left to grow and set for bloom. By the middle or end of September they should be lifted carefully for potting, in order to secure good-sized balls of earth round the plants. They should then be placed where they can receive a little bottom-heat and kept close for a time, after which they should be put into a cool stove or intermediate house for the winter, and in which they should have a light position near the glass. Bouvardias were at one time treated as ordinary greenhouse plants, but they never attained the same state of perfection as when grown freely by planting them out, and subjecting them to a fair amount of heat during the winter. Cuttings may still be put in, and, if subjected to a strong moist heat, will soon be rooted and fit for planting out. They are such useful, free-blooming plants, and afford such a variety of soft, delicate-coloured flowers so suitable for cutting or table decoration, that no garden having proper accommodation for them should be without at least two or three varieties. The best to grow are *B. Hogarthi*, elegans, *Queen of Roses*, *Maiden-blush*, *Vreelandi*, *Jasminiflora*, and *Bridal Wreath*.

Stove and Greenhouse Ferns.

As the young fronds of these have now, in a great measure, attained their full size, more air must be gradually admitted to stiffen and harden the growth, which will render it more lasting if used in a cut state. Ferns are frequently kept too hot and close to be of any great use for cutting, or for the plants to be of much value for any other purpose than to remain in the house in which they are grown; but if subjected to a moderate amount of light, with as little shade as possible, they will be found in a much better condition at the end of the season and less susceptible to insects, such as scale and thrips, that are sure to attack them when subjected to unnecessary heat. To keep the atmosphere in a moist, healthy state, the plants should be syringed every afternoon just after closing the house, unless the weather should be dull and unfavourable, under which circumstances damping the floors or other available surfaces will suffice. Much watchfulness will now be needed to see that they do not become dry at the root, as when that occurs in a sufficient degree to cause flagging, the young fronds seldom recover. Tree Ferns require special care in this direction, as valuable plants may be spoiled for the season while the growth is young and tender, and the loss of a single frond causes a great disfigurement. If they be properly drained, water should be daily poured down their stems, or else they should be freely syringed.—J. SHEPPARD, *Wolverstone Park*.

Orchids:

Many of the *Cattleyas* and *Odontoglossums* will now be in flower, and should be placed in a cool, dry situation; if they be grown on a large scale, there should always be a small house or lobby adjoining the Orchid-houses for their reception when in flower, and the door of

the Orchid-house properly so called should open into it. By this means the outer air is not admitted. Even where only a few *Orobid*s are grown, a suitable place should be found for them when in bloom, otherwise plants which should last a month in flower will be destroyed in a week by being left in a damp growing-house. After the *Cattleyas* are out of flower, place them in a dry, airy, cool house to rest, giving them only sufficient water to prevent them from shrivelling. The *Odontoglossums* of the *Alexandræ* class will probably be a little shrivelled after the flowering is over, but they should not be rested like the *Cattleyas*; on the contrary, they should be placed in the cool *Odontoglossum*-house, where they will at once begin to grow, and should be freely supplied with water, and treated like those which are now growing. Plants of *Dendrobium Falconeri* lately imported have flowered freely with me, and exhibit considerable variety; about twenty plants of this species, which I had in the cold *Odontoglossum*-house, that sometimes fell as low as 40° last winter, either have flowered or are flowering; as soon as the plants are out of bloom they should be put in a warmer house, and, if possible, hung over the pathway and well syringed morning and afternoon; carefully attend to air and shade. The temperatures for *Orchids* during the month of June should be—*East India* or warm house, from 75° to 80° by day and 70° at night; *Cattleya* or intermediate house, from 70° to 75° by day and 65° at night; *Odontoglossum* or cool house, from 60° to 65° by day and 55° at night; the higher day temperatures are for sun-heat, and by this means the houses may even be allowed to get a few degrees higher, but care should be taken to increase the moisture in the atmosphere at such times by throwing water under the stages, &c. Those who have but one house should treat it as an intermediate house, and arrange the plants in the cooler or warmer end as they may require warm or cool treatment.—JAMES O'BRIEN.

Roses.

Owing to the cold frosty winds which we have lately experienced the foliage of many of the more tender kinds of *Roses* has sustained considerable injury. Even *Maréchal Niel* has in many cases suffered from this cause, both shoots and flower-buds being much damaged. Where such has occurred the best plan is to encourage free growth. If kept clean by means of occasionally syringing, and watered with liquid manure about twice a week, they will soon outgrow their unhealthy condition. *Roses* on cordons, on ornamental trellises, and on lattice work, should be trained so as to have both blooms and foliage evenly spread over the whole surface requiring to be covered. Remove at once all spurious growth, and check any over-luxuriant shoots, both on standard or dwarf-trained trees, in order that the sap may be thrown into the flowering shoots. Dig up all suckers and tie and thin out the heads of *Hybrid Perpetuals* where too thickly wooded. Support young buds inserted last season so as to protect them from being blown off or broken by storms; shorten back the growth above the buds in order to throw as much strength into them as possible. If the bud itself be very robust, it may be allowed to flower, but if weak, remove the bloom. In most cases it is, however, best to pick out the bloom unless it is wanted for exhibition purposes, first flowers from recently-worked *Briers* being often very large and fine. If good bushy heads be wanted, stop the shoots as soon as they have made four leaves.—H. G.

Kitchen Garden.

Work now presses in every department; it will therefore be difficult to do everything at the right time; nothing should, however, be allowed to interfere with the thinning out of crops, or the planting out of *Celery*, *Cauliflower*, *Cabbage*, *Broccoli*, *Lettuce*, &c., during showery weather, as then much more of this kind of work can be done in a given time, and in a much more satisfactory manner than when the weather is dry. The recent rains have been most beneficial for all such operations, and *Carrots*, *Leeks*, *Salsafy*, *Scorzoner*a, and *Beet*, will require to undergo the requisite thinnings, which may also be planted out if desired. On rich ground *Beet* is apt to grow too large, in which case transplantation is necessary to check growth. As soon as *Onions* are thinned, and when there is the prospect of a shower, give them a dusting of dry soot: this will prevent any attack of grub that may be imminent, and it also enriches the ground. To ensure large bulbs autumn-sown *Onions* should at this time be dressed with *Gnano*, and well watered, or deluged with sewage, of which they are not easily satiated, and the same remark will apply to *Cauliflowers* and *Lettuce*; the two varieties of the latter that we grow here for summer supply do not require tying to blanch them, as both kinds heart like the hardest *Cabbage* without that operation, the sorts are *Sutton's Superb* and *Blonde de Berlin* (*Cabbage*). Our rule is to plant the first batch of *Snow's Broccoli* on ground that has been cleared of the earliest *Potatoes*; but the season being so late, these will not be ready to be dug for some time yet; consequently the

plants must be pricked off in a cool position, and transplanted with good balls of earth as the *Potatoes* are lifted. The ground does not require digging, the "clubbing" of *Broccoli* very rarely occurring in firm ground. Late sorts of *Broccoli* should now be sown, and the first batch of that invaluable *Cauliflower*, *Veitch's Autumn Giant*, be planted out, and a further sowing should now be made and grown on without check to produce a supply until Christmas. The early *Cauliflowers* are now turning in, and should the weather become hot, they will be quickly over; it will, therefore, be necessary to eke out the supply by lifting some of them when ready, and heeling them in under the shade of a north wall, or in a cool shed; they can also be preserved for some days longer in the same positions by partially lifting them with a fork, which, of course, stops growth, but a sufficiency of roots remain to keep them in condition for some time longer. As soon as all are cleared, a late crop of *French Beans* should be sown thereon, as no ground should ever remain idle, but every crop be made, so to speak, preparatory to the succeeding one. Successful plantings of *Cauliflowers* will require to be freely watered, much of which labour can be saved by mulchings of litter or grass, and it is real economy of labour to adopt this practice at the season for all kitchen garden crops. *Peas*, *Runner Beans*, *Cauliflowers*, and *Lettuce*, on our light soil all but refuse to grow without mulchings, and on heavy soils they are equally valuable to prevent the soil from baking and cracking. *Runner Beans* will now require staking, and as there is no good reason why they should be allowed to grow out of one's reach, stake them in the same manner as *Peas*, and pinch out the points of the bines when midway up the stakes; this will cause them to branch out, and (I think) makes them more prolific than if allowed to grow their full length. They do almost as well without stakes of any kind; we always grow some on a raised north border, and by keeping them pinched, and the *Beans* picked as soon as fit, I have for several years secured a supply the whole season through without successional sowings. The same treatment is not of course suited to dwarf *French Beans*, and therefore a small batch of these should be sown weekly to the end of the month. In the autumn *Lettuce* and *Endive* in quantity are always in great request where salads are valued, and now is the time to prepare for a supply. *Endive*, if sown too early, is apt to go to seed, and to obviate this the first sowing should be made on a north or east border, and allowed to remain where sown; later sowings will require warmer aspects. The best *Lettuce* for late autumn and winter supply is the *Black-seeded Bath Cos*; the first sowing of it should not be made till the end of the month, as the kinds above mentioned, and many others, are better suited for summer and early autumn use. The following may now be planted out:—*Capsicums* on spare places under south walls, a plan much preferable to growing them in pots, and there is no comparison as regards produce; *Tomatoes* also do well in such positions, but they are such gross feeders that it is ruinous to wall trees to plant near them; they should therefore be planted in the warmest and most sheltered part of the garden, and trained to a trellis: on a sloping bank with a south aspect, and a few sticks laid for them to rest on they thrive well. The soil for them should not be too rich, as then the tendency is to grow rather than fruit. Tender kinds of herbs may now be planted out, such as *Sweet Basil*, *Sweet Marjoram*, *Knotted Marjoram*, and *Savory*, for which any position is suitable if the soil be moderately rich: from 6 in. to 9 in. is ample room between the plants. *Chervil* requires to be sown several times in the course of the season, as it soon goes to seed; it should be treated in the same way as *Mustard* and *Cress*, only sown at longer intervals. Now that the garden is fully cropped the appearance of it will be much improved if the edgings and walks be kept trimmed and neat. Box edgings should therefore now be clipped, and if *Box* or *Tiles* be not used, a good temporary edging may be made by sowing a row of *Parsley* or a dwarf kind of *Beet*.—W. WILDSMITH, *Heckfield*.

South Park, Chicago.—More than a thousand acres of land have been purchased for this park, upon which work was commenced in earnest about three years ago. More than fourteen miles of sewers and drains, large and small, have been laid, and more than two hundred and fifty acres of flat, marshy ground converted into the finest lawn. The whole amount expended during that year was more than \$150,000. The trees planted along the drive-ways are mostly *Elms*, but the cut-leaved weeping *Birch* has been found to succeed admirably, and many fine specimens of that beautiful tree were noticed. The plan includes a Botanic Garden, which was commenced in the spring of 1875, and in which, under the care of Prof. H. A. Badcock, more than three thousand species of plants have already been collected. The whole of these extensive parks is, however, but a part of a general plan to surround the city with a system of parks and boulevards, forming a drive of twenty-five miles in extent.

THE INFLUENCE OF BEAUTY.

MISS MIRANDA HILL lately delivered a lecture on "The Influence of Beauty on the Life and Health of the Nation," in the rooms of the Social Science Association, Adam Street, Adelphi. Miss Hill observed that the present was an age when men were seeking after beauty—the improvement in architecture, the increasing love of pictures and of music, the desire for decoration of churches, all showed that beauty was felt as a good in itself. Those who had had the happiness of passing their childhood in the country could fail to trace some of their boldest thoughts to impressions made by the scenes they then saw around them. All beauty of art, whether of music, or painting, or architecture, had in different degrees, perhaps, the same effect. To those who recognised a power for good in nature, poetry, painting, or music, it became a bounden duty to share with others the advantages they were able to obtain for themselves. Miss Hill then proceeded to speak of what it was possible for the higher classes and the better educated to do in the way of bringing healthy and ennobling influences to bear on those whose lives were for the most part laborious, monotonous, and generally destitute of any kind of amusement, except the merely exciting and sensational. She urged the giving of poor people, especially children, as much healthy outdoor amusement as possible, and spoke approvingly of the work done by the Ladies' Sanitary Association in organising the "park parties" for poor children. For grown-up people expeditions a little way into the country on Saturday afternoons would be a great good. There ought to be as many open spaces near to the homes of the townspeople as possible; and those spaces should be planted with trees and made beautiful with Grass and flowers. If leave could be obtained to lay out the now disused churchyards, and make them quiet resting-places for the living, it would be putting them to the best possible use. More general use for the benefit of the poor, she thought, might be made of the squares. As the beauty of the country was being allowed to recede more and more, towns ought to be improved as much as possible by beauty being brought into them. The cultivation of flowers had done much good, but that and the cultivation of window plants and plants out-of-doors ought to be extended. Great was the importance of making the towns more beautiful. Every year, as the population increased, the need of wild, open country increased. Outlets were wanted for the vast city populations—places where they could breathe freely, where they could look upon the wonderful works of Nature, where they could feel the blessedness of silence and solitude for a few hours. The rapid disappearance of so much of the wild country by the spread of building rendered it needful that all which could be saved for the higher enjoyment of the people should be saved.—"Queen."

NOTES AND QUESTIONS—VARIOUS.

Raising Rhododendrons from Seed.—I have been unsuccessful with seedling Rhododendrons, which I cannot get past the second or third leaf. The last I had remained nearly three months in the second leaf stage, and then, by degrees, grew smaller. How should I treat them?—N.W. JESSUP. [In this country no trouble is experienced in raising Rhododendrons from seed. We prepare the seed-bed out-of-doors, using fir or some such peaty soil, mixed with friable loam, and sow in the month of May, keeping the young plants, when up, well watered and shaded.—J. W.]

New Large-flowered White Lilac.—Amongst shrubs at present in flower and worthy of special notice is *Lilac alba grandiflora*, the individual blooms of which are nearly twice as large as those of the old white kind. The bunch is about the same size, but the variety seems to possess the valuable quality of blooming in the form of young dwarf plants. The old White Lilac it may be remembered begins to flower only when the plants have attained a considerable size and height.—G. PAUL, *The Old Nurseries, Chessnut*.

Evergreens for Damp Situations.—Your correspondent (see p. 482) might try some of the following:—*Daphne Laureola*, *Rhododendron ponticum*, *Arctostaphylos*, *Box* of various sorts, various kinds of *Mahonias*, *Butcher's Broom*, and *Green Holly*; without, however, seeing the situation in question it is impossible to specify exactly what would be suitable.—M.

The Best Garden Mouse-trap.—Permit me to correct an error which appears in my communication on this subject (see p. 490). In describing the glazed pots I am made to say about the size of a 24-in. pot; it should have been a 24-sized pot. I may add that it might be a convenience and I may also state that the trap may be used in root cellars, seed or fruit rooms, &c., by placing it on the floor placed in a mound of dry earth, sawdust, or Cocoa-nut fibre.—HARVEY A. WOOD, *Willow Lodge, Mitcham*.

Design for Horton Park, Bradford.—The "Bradford Observer" states that the offer by the Recreation Grounds Committee of the Bradford Town Council of two premiums of 100 guineas and 50 guineas respectively for the first and second best designs for the laying-out of Horton Park, brought into the field twenty-eight competitors, and, after careful consideration, the committee decided to recommend to the Council the design bearing the motto "Toujours prêt" as being deserving of the first premium. It is generally understood that Mr. William Gay, landscape-gardener, of Bradford, is the author of the first design.

SOCIETIES AND EXHIBITIONS.

ROYAL AQUARIUM FLOWER SHOW.

MAY 30 & 31.

THIS exhibition was the largest that has taken place this season, a fact attributable more to the liberal prizes offered on the occasion than to the suitability of the Aquarium for flower shows, for of all places it is the worst for displaying to advantage the beauty of plants and flowers. Everything was, however, done that could be done to make the show as attractive, in an artistic sense, as the site would allow, but the grouping, excellent though it was, was not both judges and reporters much extra labour and not a little dissatisfaction on the part of many of the exhibitors; indeed, in one or two instances, the decision of the judges was successfully disputed, a result arising entirely from the difficulty of comparing and properly judging groups of plants set up in different ways and in different parts of the building. Among the more remarkable plants shown we may allude to a specimen of *Lxora coccinea* in Dr. Woodman's group of stove and greenhouse plants, sent from Exeter, and also to a remarkably well-bloomed plant of *Stephanotis floribunda* in the same collection; both of these were deserving of all praise, being excellent examples of really good culture and careful packing. The plant of *Drapacophyllum gracile*, sent by Messrs. Jackson & Sons, of Kingston, was also a well-nigh perfect specimen of its kind. Orchids were fairly well represented, but they were placed too close to the pot Roses and Azaleas to be seen to advantage; indeed, of all plants Orchids require the most taste and care in arrangement as regards effect; they should only be contrasted with Ferns and similar plants, and never with flowers possessing bright and vivid colours. Among Orchids individually fine may be named *Anguloa Clowesi*, *Calanthe variegata*, *Cattleya Mendellii*, *Mastveallia Veitchii*, *M. Harryana*, and *Dendrobium litiflorum* in the first prize group, which was sent by Mr. O. O. Wrigley, from Bridge Hall, Bury, Mr. F. G. Wilkins, Leyton, furnished excellent specimens of *Cypripedium Stonei*, *Epidendrum vittatum majus*, *Odontoglossum Alexandræ*, *O. Pescatorei*, and *O. vexillarium*, and also a good example of *Dendrobium Devonianum*. Mr. J. Douglas, Loxford Hall, had a well-bloomed plant of *Cattleya Warneri* in capital condition. The pot Roses from Mr. Charles Turner and Messrs. Paul & Son, though attractive, were rather past their best. New plants were shown in admirable condition by Mr. W. Bull, who obtained first prizes in all the classes, and also in those devoted to Crotons, *Dracænas*, and Palms, his plants in every case being remarkable for freshness of aspect and careful culture. Mr. B. S. Williams, Messrs. Rollison & Sons, and Mr. H. Ley also sent good collections of new or rare plants. New plants, exhibited for the first time, were not particularly remarkable. Among those likely to be of permanent value may be noticed *Martinezia Roezlii*, a robust Palm with rich olive-green bilobed foliage set on short petioles and with rufous spines. *Bomarea Carderi*, a pink-flowered creeping *mauve*, is also new. *Gunnera granatensis*, an example of which was shown, is a large habitated plant, with dark green leaves, similar in shape to those of *Anthurium regale*, the petioles being very scabrous at the base. *Croton Williamsii*, although not strikingly handsome, is the most distinct break we have yet seen among new varieties, the broad and oblong green leaves being splashed with creamy yellow and silvery grey. *Phajus fimbriatus* is evidently a robust and tall-growing form of the old *P. albus*, its pseudo-bulbs being 5 ft. in length, and the flowers large in proportion. One of the most effective of all new Palms is *Astrocaryum murmurans*, a kind with dark glossy, bilobed, gracefully arching leaves, silvery beneath the downy petioles, being armed with stout, glossy brown spines. A new robust-growing *Aralia*, named *A. splendissima*, also deserves notice. It has pinnate leaves, which are each fully a yard in length, radiating from the slender central stem. The classes for Azaleas, Heaths, and *Pelargoniums*, were filled with well-grown plants, and several good collections of Ferns, Palms, and other fine foliaged plants were distributed throughout the building.

Certificates.—These were awarded to the following new plants:—

***Cattleya Buntii* (Low & Co.).**—A stout-habited and distinct *Cattleya*, something in the way of *C. gigas*, but with white flowers, the lips of which are suffused in the throat with lemon yellow. The flowers are very large and beautiful, and the plant is sure to become popular.

***Pellaea Ornithopus* (Rollison & Son).**—A dwarf-habited Fern, having glaucous, finely-divided fronds, from 3 in. to 5 in. in length, these being produced in dense tufts, which measure from 5 in. to 6 in. across. It is very pretty and distinct, and is well deserving of culture.

***Azalea indica imbricata* (Mr. R. Thornton).**—A pleasing variety of considerable merit, having white or bluish-tinted flowers of good form and substance. It is a plant which well deserves attention both for decorative purposes and for exhibition.

***Sarracenia Williamsii* (B. S. Williams).**—A strong-growing plant, something like *S. flava*, but of more robust appearance. It is a distinct and well-nigh new kind, which, when more fully developed, promises to be an effective exhibition plant.

***Adiantum Williamsii* (B. S. Williams).**—A distinct and handsome stove Fern, bearing dense green fronds in tufts measuring a foot or more across. The young growth is of a tender and pleasing green tint suffused with red. It looks as if it would become a decorative Fern of the highest value.

***Pelargonium zonale*, Wonderful (G. Smith).**—A most effective double-flowered sport from *P. Vesuvius*, which has already been certificated at all London shows. For pot culture or bedding it is

decidedly the best variety of its class, and is already deservedly popular as a thoroughly useful decorative plant.

Silver tricolor Pelargonium Empress of India (J. Pestridge).—A robust-habited and brightly tinted-silver tricolor, above average merit, and one which promises to be very useful, either as a pot plant or for edging purposes.

Brompton Stock, New Giant White (R. Dean).—A strong and compact-habited variety, bearing perfectly double white flowers in great profusion. It well deserves culture, not only for decorative purposes, but also for supplying cut bloom.

New Plants—The principal class for new plants, in or out of commerce, Mr. W. Bull, of Chelsea, was first, with one of the best groups we have yet seen, although, in this case, rather hidden under plants of a more ordinary kind. In Mr. Bull's group we remarked *Bertonia superbiensis*, with dark-velvety ruby-spotted foliage; *Croton spirale* and *C. Disraeli*, both effective kinds; a large and noble plant of the almost unique *Pritchardia grandis*; the zebra-striped *Dracaena Goldiana*, and the dark purple *Arcotarpus Cannoni*; the elegant fresh green *Pandanus princeps*, and two or three *Dracaenas*. Mr. B. S. Williams was second with the handsome *Aralia Veitchii* elegantissima, *Anemia tessellata*, *Gleichenia repustata*, glaucensis, *Dracaena Hibberdii*, *Aralia elegantissima*, and several new Palms and Cycads. Messrs. Rollison and Sons were third with *Vriesea reticulata*, *Pellaea Ornithopus*, *Goodyera velutina*, and others. In the class for six new or rare plants, not before shown, Mr. W. Bull was first, with beautiful specimens of *Smilax Shuttleworthii*, *Gunnera granatensis*, a species with large *Alocasia*-like leaves, having scabrous petioles; *Diefenbachia majestica*, evidently only a broad-leaved and good form of *D. princeps*; a large-growing *Gymnogramma* named *G. Chelsoni*, and a new golden-blotched *Croton*. Mr. B. S. Williams had *Croton Williamsii*, and *C. Victoria*, an effective crimson-stemmed golden variegated form, something like *C. Weismannii* in habit; *Panax laciniatum*, a cut-leaved species of elegant habit; *Ficus ovalifolia marmorata*, the large-leaved *Jambosa acida*; and *Phajus fimbriatus*, a large form of the better known *P. albus*. In the class for six new plants (Orchids excluded), Mr. W. Bull was first with *Croton formosum*, which is said to be a seedling from *Veitchii*, fertilised with pollen from *C. Weismannii*, *Diefenbachia triumphans*, *Dracaena Goldiana*, *Sadleria cyathoides*, an elegant fresh green plant, having pinnate leaves and in length, the pinnae being cut, and of a dark glossy green colour. In the class for three new or rare plants of never before exhibited, Mr. Bull was again first with *Diefenbachia princeps*, a long-leaved kind, having grey-green foliage, feathered with silver down the midrib, and irregularly, but distinctly blotched with apple-green. *Martinezia Roezlii*, a deep green Palm, fan-leaved in its present state, but doubtless irregularly pinnate when older, the base of its mid-rib and petioles being covered with red rufous spines; and *Bomarea Carderii*, a scandent *Amaryllid*, with smooth oval leaves, and bright, green-tipped, dark-speckled flowers. Mr. B. S. Williams was second with a dwarf *Ixora* named *I. multiflora*; and a new pedate-leaved *Anturium*, having reddish-tinted young growth; and a very distinct new *Croton* named *C. Williamsii*. This has glossy, bright green leaves, irregularly blotched, and margined with creamy-yellow. In the class for three new plants (Orchids excluded) Mr. W. Bull was once more in the foremost rank with *Diefenbachia Carderii*, a distinct plant, with dark foliage boldly blotched with apple green; *Dracaena Goldiana*, and the cut-leaved new *Caledonia Aralia spectabilis*. Mr. B. S. Williams was second with *Woodwardia radicans cristata*, *Zamia intermedia*, and *Astrocarum murpureum*, a plant with glossy green bilobed leaves, silvery beneath, the petioles being also silvery, and set with stout, brown, tooth-like spines.

Stove and Greenhouse Plants.—The best group of these came from Messrs. Lucombe, Pince, & Co., of Exeter, who had shapely and naturally trained plants of *Aphelexis macrantha rosea*, *Ixora coccinea* in splendid condition, and *Stephanotis floribunda*, a mass of fragrant white flowers and fresh green foliage. From the same firm also came good plants of *Erica tricolor impressa*, *E. Lindleyana*, and large examples of *Azalea Trotteriana* (bright carmine), *A. criterion* (soft salmon-rose and white), and a well-bloomed plant of *Clerodendron Balfourianum*. The second prize was awarded to Messrs. Jackson & Sons, of Kingston, who had a superb specimen of *Dracophyllum gracile*, *Statisia profusa*, one of the best of all the flowered exhibition plants; a very fine *Aphelexis macrantha purpurea*, the scarlet-spined *Anthurium*, and several good *Heaths*, and *Epacrises*. Mr. B. S. Williams contributed a well-arranged group, to which a third prize was awarded. In the amateurs' class the premier award was assigned to Mr. J. Ward, of Leyton, who had, amongst others, good plants of *Erica ventricosa coccinea mixta*, *Ixora Williamsii*, and a very remarkable large-spined *Anthurium Scherzerianum*. Mr. Bull was first in the class for twelve Palms, the most distinct among them being *Chamerops humilis nivea*, *Livistona altissima*, *Cocos Weddelliana*, *Calamus ciliaris*, and *Licuala peltata*. In the class for six *Crotons* Mr. Bull was again first with large and admirably coloured specimens of *C. Cooperii*, *C. Imperiale*, *C. spirale*, *C. Weismannii*, and *C. majesticum*. Mr. B. S. Williams had large and highly coloured plants, which obtained the third prize, Mr. J. Harrow, gardener to H. Bessemer, Esq., Denmark Hill, had also six well-grown plants.

Orchids.—When a prize of £50 is offered for twenty specimens we expect to see some good plants shown, and on this occasion we were not disappointed, the best group being that furnished by Mr. C. O. Wrigley, of Bridge Hall, Bury. Among these Lancashire plants we noted the *Clivia magnifica* and carmine forms of *Masdevallia Harryana*, *Angulosa Clowesi*, bearing twenty or thirty yellow Tulip-like flowers; a good plant of the grassy-leaved *Odontoglossum Phalaenopsis*, and a

vigorous example of the chaste, white-sepalled, purple-lipped *Catleya Mendellii*, bearing twelve flowers and buds; not the least inconspicuous plant in this group was a well-grown specimen of the old *Thunia alba*, bearing seven spikes of white flowers. Here, also, was a fine mass of bearing *Thunia* flowers, and a good specimen of the plant of M. Linden's *Masdevallia*, bearing about thirty flowers, also a plant of M. Veitchii, bearing twenty flowers and buds; and, in addition, splendid masses of *Dendrobium lituiflorum* and *Odontoglossum Alexandra*, a fine mass, bearing twelve spikes, the beauty of this group being further enhanced by a well-flowered *Calanthe veratrifolia*, bearing from twenty to thirty spikes; a good *Vanda suavis*, with four spikes; *Cyrtipedium candatum*, with eleven flowers, and a good pot of *C. niveum*, bearing fifteen nearly-white, lilac-spotted blossoms. The second prize was awarded to Mr. W. Bull, who had smaller specimens, but equally well grown and well bloomed. In this group we noted some excellent plants of *Dendrobium McCarthiae* and the musk-scented *D. Devonianum*, also a fine plant of the rosy-purple *D. Dayanum*, *Odontoglossum Pescatorei*, bearing a large-branched spike of twenty-eight flowers; *Epidendrum vitellinum majus*, furnished with three fine spikes of bright orange-scarlet flowers, and excellent examples of *Odontoglossum Phalaenopsis*, *Masdevallia Veitchii*, a very fine *Cyrtipedium Stonei*, and an equally fine *Dendrobium thyrsoiflorum*; nor must we overlook a vigorous plant of the Foxbrush *Aerides* (*A. Feldingi*), bearing three fine spikes. The third prize was awarded to Mr. J. Douglas, of Colford Hall, Ilford, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. Phalaenopsis*, *Lidford*, among whose plants we observed striking specimens of *Catleya Warneri*, *Saccolabium ampullaceum*, bearing three spikes of purplish flowers; *Masdevallia Veitchii*, also with three flowers; and two very distinct forms of *M. Harryana*, the one with carmine, and the other with bright lilac-shot flowers. In the same group was *Cyrtipedium villosum*, well bloomed, *C. spectabile* with six spikes, *Odontoglossum Andersonianum*, and its ally *O. Alexandra*, together with a well-bloomed *Dendrobium Bensonianum*. Among the plants shown in competition for the smaller prizes in other classes, Mr. W. Bull was first with *O. "This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE MILTONIA-LIKE ODONTOGLOSSUMS.

THIS very beautiful section of the genus *Odontoglossum* so closely resembles the *Miltonia* in the appearance of their flowers that the first introduced (*O. Phalenopsis*) was originally named *Miltonia pulchella*. They are distinguished by their large flat flowers (mostly white or white with various shades of rose) and their light greyish-green pseudo-bulbs and leaves, and so distinct are they in character that even the most casual observer could not fail to see that all of them belong to one class. The sorts of this section at present known are but few, but the variations in colour in the flowers of different plants of the same species lead us to suppose that there are yet more of them to be discovered, and to hope that the day is not far distant when we shall receive other new and beautiful allied varieties. The representatives of this class are found to require under cultivation different treatment from most of the other *Odontoglossum*s, and as some cultivators, unaware of that fact, have placed the newly-arrived *O. vexillarium*, &c., in the cold *Odontoglossum*-house, a few remarks on their culture may not be out of place.

ODONTOGLOSSUM VEXILLARIUM.—This splendid variety, upon which the energies of so many collectors have been concentrated for a long time, and, until recently with such ill-success, has now been received in this country in sufficient quantity to place it within the reach of all; it was first found growing on the western slopes of the Andes in New Granada by the late Mr. Bowman, who sent some specimens of it to Europe, which unfortunately died during their transit; since that time several importations have been received, but among them very few living plants until within the last few weeks, when they seem to have arrived both in quantity and in good condition; it is, without doubt, the finest *Odontoglossum* ever imported, and grows from 8 in. to 12 in. in height; the pseudo-bulbs (which are from 1 to 2 in. in height, of a light greyish-green, oblong and rather flat, with a single leaf at the top, and from 4 in. to 6 in. at the base), are soft, and have but little fibre in them; hence the plants have been found so difficult of importation in a vigorous state; the leaves are of the same colour as the pseudo-bulbs, often tinged with rose, from $\frac{3}{4}$ in. to $1\frac{1}{2}$ in. in width, elliptic-lanceolate, and rather acuminate at the points, and so arrange themselves as to give the plant at a distance the appearance of a *Huntleya* rather than that of an *Odontoglossum*. The flower-spikes are produced from the axils of the leaves of a mature growth, from one to three of them proceeding from each leader, each spike bearing from three to nine flowers, from 3 in. to 4 in. in length, and from 2 in. to 3 in. in width; the sepals are oval and rather pointed at the tips, of a soft rose colour, and the petals are of the same shape as the sepals, but generally of a slightly darker shade; the labellum is large, flat, and oval, deeply notched in front and narrowed at the base, where it again extends upwards into two small wings; it is of a delicate rose colour, lighter round the edge; the base of the labellum is white with a yellow blotch streaked with crimson, the white often running in a distinct and gradually narrowing band down to the cleft in front. From this description let us hope that many who have never seen the plant in flower, or even a figure of it, may be able to form some idea of its extraordinary beauty when in flower—a beauty so great as to earn for it the well-merited title of the Queen of Orchids. *O. vexillarium* succeeds best, and produces flowers of a better quality and in greater abundance when grown in the warm end of an intermediate or Cattleya-house all the year round, than in the old-fashioned *Odontoglossum*-house, and placed in such a position that air can be freely admitted without the plants being in a draught. It is best grown in a well-drained pot, in a mixture of equal proportions of good fibry peat, and living Sphagnum Moss, keeping the plants well above the rims of the pots, and top-dressing with living Sphagnum; a copious supply of

rain-water should be given from the present time, when the plants are making new growth until the pseudo-bulbs are fully formed, afterwards administering a limited application during the season of rest, for this *Odontoglossum*, in common with the others in its section, does not thrive if allowed to get quite dry at any time; it also requires plenty of air and light without the direct rays of the sun, and if a full-grown specimen be put on the stage in the Orchid-house, it should be placed on an inverted flower-pot to bring it nearer to the glass; but if it be a small specimen or a freshly imported plant, it will be better to suspend the pot with the plant in it by means of wires or fasten it into a hanging basket with Moss. It is a very free-growing and profuse-flowering plant, and if but ordinary care be taken and the temperature be that of a genial intermediate house, there is little fear of losing it. Some Orchid-growers place this plant in the East India house during the growing season, but although it succeeds better there than in the cold *Odontoglossum* house, it is more likely to make weak unstable growths, and is found to be more liable to the attacks of thrips, &c., than when grown as recommended above.

O. WARSCEWICZI.—This very desirable plant bears a striking resemblance to *O. vexillarium*, except in the colour of its flowers and its slightly narrower leaves; in general appearance it is so similar to the latter-named variety that it is difficult to distinguish them apart when not in flower. It is a native of Costa Rica, and was first found by that discoverer of so many beautiful plants, the late Joseph von Warscewicz, a Polish gentleman, but the plants were so scarce, even in their native habitats, and of such a peculiar nature, that even he despaired of ever being enabled to forward any to Europe alive. Since that time several collectors have essayed to accomplish the task, but have failed, until at last Senor Endres succeeded in bringing a few over in good condition, the greater part of which are in the possession of the Messrs. Veitch, of Chelsea, or in cultivation elsewhere in this country. The flowers, which are not quite so large as those of *O. vexillarium*, are borne from three to five on a spike; their prevailing colour is a soft creamy-white, the sepals having small purple marks close to the column, the petals and labellum having blotches of various shades of purple at their bases and a blotch of yellow at the base of the labellum, the disposition and intensity of the colouring varying very much in different specimens. It thrives well when treated in precisely the same manner as that recommended for *O. vexillarium*, but care should be taken to keep it free from thrips, &c., by frequent sponging, and never to fumigate a house in which it is placed, for nothing is more injurious to the whole of this class of *Odontoglossum*s.

O. ROEZLI is a beautiful variety, introduced by M. Roelz from New Granada; it grows about 9 in. in height; the pseudo-bulbs are narrower than those of *O. vexillarium*, which they resemble in other respects. The leaves, which are gracefully arranged, are generally about $\frac{1}{2}$ in. in width; the flowers, which are borne well above the leaves on rather erect spikes, and number from two to four on a spike, are each about 3 in. in length and $2\frac{1}{2}$ in. in width, and have much the same outline as those of *O. Phalenopsis*, and are delightfully fragrant; they vary greatly in the colour of the markings, some of the plants having pure white flowers, others white with a distinct dark purple blotch at the base of each petal, and a yellow blotch at the base of the labellum, while others are marked with yellow or orange at the base of each petal and the labellum, the colouring in the flowers of many plants varying in shades until a great number of varieties may be obtained from a single importation; but all are alike lovely, and the difference in the colouring rather enhances the value of the plant than otherwise, for the grower of several specimens can have them all differing from each other. This *Odontoglossum* is neither so costly nor so difficult to procure as the two previously described, a large assortment of them being procurable at almost all the large London nurseries. It should be grown in pots in good fibry peat, or fibry peat and Sphagnum Moss, and treated in the same way as the *O. vexillarium*, giving a plentiful supply of air and water during the growing season.

O. PHALENOPSIS.—This compact-growing species is the gem of its class, for, if not so majestic in appearance as the *O. vexillarium*, it is equally attractive, the large size and profu-

sion of its flowers, in proportion to the small bulbs and leaves, always exciting surprise and admiration. It is a native of Oceana, where it was discovered by M. Schlim, who first sent it to Europe; it was exhibited in London about twenty years ago, and since that time many importations of it have been received, of which the greater portion have succumbed to bad management; at present, however, its culture is better understood, and well-grown specimens are by no means uncommon—one in particular, exhibited by Mr. Ward at several exhibitions in London this year, may be regarded as a triumph of cultural skill. The plant is of tufted growth, from 6 in. to 9 in. in height, and unlike any of the others of its section in appearance: the pseudo-bulbs are from 1 in. to 1½ in. in height, oval, rather pointed, and compressed, bearing a single leaf at the top, and one on each side at the base of each pseudo-bulb; the leaves are less than ½ in. in width, grass-like and pale green; the peduncles rise from the base of the bulbs, and bear from one to four flowers on each; the flowers are about 2½ in. in length, and 2 in. in width; sepals ovate, somewhat pointed, pure white; petals same shape and colour, but rather broader; the labellum is flat, large, and panduriform, white marked with yellow in the middle, rosy-lilac lines radiating from the centre into the upper portion, the anterior part of the labellum being blotched and streaked with rose, a broad irregular margin of white running round it. The shades of colour differ in brightness in some plants of this species, but want of sufficient light when the flowers are forming and expanding is more frequently the cause of this than anything else. It should be grown with the other varieties enumerated in pots in fibry peat and top-dressed with Sphagnum Moss; and after the pseudo-bulbs are matured it should be rested in a drier and cooler house, but water should not be withheld, nor the temperature allowed to get too low.

These four varieties form a distinct and beautiful section of the genus *Odontoglossum*; they are all epiphytes, flowering generally in May and June, lasting about a month in perfection, and beginning their new growths soon after the flowering season is over. They look better, particularly *O. Phalaenopsis* and *O. Roezlii*, when grown in deep pans or half-pots; the ordinary flower-pot, being unnecessarily deep, detracts from the compact appearance of the plants. The chief requisites for the successful development of the plants of this section are light, air, and a temperate heat at all times, a plentiful supply of water and a moist atmosphere during the growing season, discreetly limiting the supply of water, and keeping the atmosphere rather dry during the season of rest. The plants should always be placed as near the glass as convenient, and frequently sponged.

JAMES O'BRIEN.

THINNING OUT OF FRUIT.

It is a popular notion that nearly all, if not all, fruit trees will only bear full crops every alternate year, and that this is a fixed law of nature. There is no real foundation for any such notion; for if the trees are properly cultivated they will bear regular crops of fruit every year, unless heavy frosts or other atmospheric disturbances injure the trees or destroy the blossoms. All cultivators who are proficients in their business understand this, and provide a regular supply of fruit, year by year, from the same trees. The three principal means by which they produce such results are by pruning, manuring, and thinning out the fruit. In all ligneous and in many herbaceous plants the flowers, fruit, and seeds are produced by the stores of material laid up within the plant during the previous season. Hence the necessity of encouraging and perfecting a strong and healthy growth, if we expect to obtain a fine crop of fruit the ensuing year. This cannot be obtained if the tree be exhausted by producing an overcrop. When allowed to overbear, it takes a whole year to recuperate and gather strength to bear another crop, and from this arises the fallacy that fruit trees can only bear a full crop of fruit on alternate years. The well-known law of animal life, that the reproduction of the species is the ultimate destruction of the individual, holds, according to "Harper's Bazaar," equally good in the vegetable world. But the exhaustive effects of this reproduction are found to be not so much in the pulp of the fruit and the sugar or other matters it contains as in the number of seeds or future germs of life which the plant produces. If the plant be prevented from reproducing itself in this way, its life may be greatly prolonged; and hence, if the flower-stems of a plant be cut off as soon as it has done flowering, the

plant will increase in size and strength much faster than if it were allowed to produce seeds. If the seed-pods on a *Rhododendron* be not cut off as soon as the flowers drop, it will not flower well the ensuing year; and by cutting off the flower-stems of many annuals as soon as they have ceased flowering, they can be kept alive for two or three years. The prevention of this exhaustion of the plant by overbearing is partly obtained by judicious pruning, but more thoroughly by thinning out the fruit to such an extent as to leave no more on it than it can reasonably carry. This, of course, requires close observation of the habits and state of the tree on which the operation is performed. As a general rule, not less than one-third, and often one-half, should be removed, as Nature, in order to guard against the many accidents to which the young plant life is liable, provides a large excess of life-germs. This operation, strangely enough, does not lessen the actual weight of the crop produced, for it will be found on experiment that, although the number of fruit is greatly reduced, yet the remainder becomes so much larger, more pulpy and saccharine, as to equal the weight of the multitude of dry, small, tasteless fruits, which would have been produced had the whole crop remained on the tree. The proper time to thin out the fruit is just when the albuminous matter in the seed begins to harden. Hence, in this latitude it is best done for the Apple and Pear toward the end of June or the beginning of July; for the Peach and Plum, as soon as the outside shell of the kernel begins to harden. Of course thinning out and pruning are not universal panaceas for producing fine crops of fruits. It will be readily seen, from what we have said, that the plant must have something from which to obtain the material to support this exhaustive process of reproduction. This can only be obtained from the soil, which the tree soon exhausts of its supply of such material, unless it is replaced by continuous but moderate manuring. We do not, as a rule, grow fruits for the seeds, but for the pulp which generally surrounds them. To obtain this, we must arrest the production of seeds, and divert the matters drawn from the soil to the production of that which we want.

FLORAL DECORATIONS FOR JUNE.

Flowers are so plentiful and so various in colour throughout June, that it is difficult to know where to stop in making a list of those most suitable for decorative purposes. For bold effects, *Rhododendrons* in shades of crimson, pink, and white are unequalled; but they are only to be used below the line of sight. *Iris*, of various shades of purple, blue, mauve, yellow, and white, have a pretty appearance when arranged together, without the admixture of other flowers; they should be furnished with their own leaves, or with some other broad sedge-like foliage. *Sweet Peas*, in variety, will soon be available, and they also look better by themselves, arranged with a few deep green Grasses than mixed with any others, unless it be *Mignonette*. Our wild Grasses and Sedges are not half so often used in vases as they deserve to be; the taller and more noble species, which are now abundant in damp and marshy places in half-dry ditches, present a most effective display, and give a degree of lightness, grace, and elegance to an arrangement of flowers that nothing else can match. *Pyrethrums* are particularly useful for groupings which are to be viewed under artificial light, since their colours look even better then, if it be possible, than by daylight. The *White Broom* is exceedingly pretty for the tops of tall vases, provided it be used sparingly.

Blue—Cornflower, *Gentiana*, *Iris*, *Myosotis*, *Nemophila*, *Pansy*.
Purple—*Anemone*, *Heliotrope*, *Iris*, *Pansy*, *Phlox*, *Sweet Pea*, *Verbena*.

Mauve—*Heath*, *Iris*, *Pansy*, *Wistaria*.

Pink—*Azalea*, *Begonia*, *Bouvardia*, *Carnation*, *Fancy Pelargonium*, *Fuchsia*, *Heath*, *Hydrangea*, *Oleander*, *Phlox*, *Pyrethrum*, *Rhodantha*, *Rhododendron*, *Rose*, *Sweet Pea*, *Verbena*, *Zonal Pelargonium*.

Crimson—*Azalea*, *Bouvardia*, *Fuchsia*, *Phlox*, *Pyrethrum*, *Rhododendron*, *Rose*, *Spiræa*, *Sweet Pea*, *Verbena*, *Wild Orchis*.

Maroon—*Clove*, *Carnation*.

Scarlet—*Anemone*, *Bouvardia*, *Carnation*, *Poppy*, *Ranunculus*, *Tropeolum*, *Verbena*, *Zonal Pelargonium*.

Orange—*Carnation*, *Erysimum*, *Eschscholtzia*, *Rose*.

Yellow—*Alyssum*, *Azalea*, *Broom*, *Double Buttercup*, *Calceolaria*, *Coronilla*, *Eschscholtzia*, *Globe-flower*, *Gorse*, *Iris*, *Rose*.

White—*Alyssum*, *Anemone*, *Aponogeton*, *Arabis*, *Arum*, *Azalea*, *Begonia*, *Bouvardia*, *Broom*, *Double Buttercup*, *Carnation*, *Chinese Primrose*, *Deutzia*, *Eucharis*, *Fancy Pelargonium*, *Gardenia*, *Guelder Rose*, *Heath*, *Lily of the Valley*, *Mock Orange*, *Myosotis*, *Pink*, *Rhodantha*, *Rhododendron*, *Solomon's Seal*, *Spiræa*, *Stephanotis*, *Sweet Pea*, *Woodruff*.

W. T. T.

NEW PLANTS, &c.

Hoodia Gordonii.—This remarkable Asclepiad was discovered near the Orange River, S. Africa, by Col. Gordon, who made a drawing on the spot, which was published in Masson's "Stapelia Nova," in 1796. For nearly half a century nothing more was known of it than this figure, which seemed so extraordinary that our Stapelia growers used to speak of it as a fiction. The plant, however, was re-discovered in quantity by Mr. Burke, a gardener of the Earl of Derby, who was sent out at that nobleman's expense, and living plants were cultivated at Knowsley, but it is not known that they flowered. In 1874, Sir H. Barkly, the Governor of the Cape, sent to Kew two fine specimens from Heukrieks, near the Orange River, one of which died, but the other arrived in perfect condition and flowered in 1875. The plant has tufted, thick, spinose, Euphorbia or columnar Cereus-like stems a foot or more in height, and towards the apices of these the large (Enothera-like) flowers are produced generally in pairs. The individual flowers are from 3 to 4 in. in diameter, and of a soft lemon-yellow colour, delicately flushed with rose. It is a most remarkable and effective plant, and when more plentiful will be popular with all growers of rare succulent plants.—"Botanical Magazine," t. 6228.

Odontoglossum tripudians.—A showy Orchid, a native of New Granada, whence it was sent to Messrs. Veitch & Sons by M. Gustave Wallis. In general appearance it resembles a small-flowered variety of *O. triumphans*, the golden-yellow sepals and petals being beautifully blotched with brownish crimson, the lip being of a pale lemon-yellow, having a large blotch of brownish purple on the disc. Although not so large or attractive as its ally, *O. triumphans*, it is a welcome addition to one of the most popular groups of cool-growing Orchids.—"Botanical Magazine," t. 6229.

Vitex Lindeni.—An inconspicuous Verbenaceous shrub from New Granada, having ternate or quinate foliole and axillary peduncles, each of which bears two soft lilac-purple streaked flowers, which closely resemble those of some *Genacras* in general appearance. It is not likely to be useful for decorative purposes.—"Botanical Magazine," t. 6230.

Calceolaria tenella.—A dwarf and interesting little Chilean species, first found by Pöppig in 1823, and since re-discovered by Bridges in sandy places and on wet rocks near the rivers of the Andes and in Valdivia, at elevations of from 4000 ft. to 5000 ft. Seeds of it were recently sent to Messrs. Veitch by their late collector, Mr. G. Downton, from which flowering plants were raised in 1873. It is thought to be quite hardy, and if so it will be a pretty ornament to the rock garden, forming dense tufts of fresh green foliage, 3 in. or 4 in. in height, in the axils of which the golden yellow crimson-streaked flowers are produced on short curved pedicels.

Arundo conspicua.—This is perhaps the most graceful of all the large-growing, ornamental Grasses. A native of New Zealand, and quite hardy in sheltered positions in the south of England. At Kew it forms a very attractive pot-plant in the succulent-house, where its graceful silvery plumes remain in beauty nearly all the year round. It was first discovered by Banks and Solander during Cook's first voyage, and abounds throughout the island of New Zealand, from the Bay of Islands to Otago and the Chatham Islands, growing in wet places, but it is found in no other part of the world. It is the *Toe Toe* and *Kakaho* of the natives, who are said to use the culms for lining their houses in the style of reed matting. The first figure of this plant appeared in the "Florist" for 1874—having been taken from a specimen 10 ft. in height, bearing forty-two of its elegant plumes. In the garden of Mr. G. F. Wilson, of Weybridge, is a specimen which flowers annually in great perfection towards the latter end of the summer. Herein lies one of the claims of the *Arundo* to rank above the *Pampas* as an ornamental plant. The *Arundo* sends up its culms and expands its feathery panicles by the end of July or the beginning of August, so that its graceful beauty can, in the average of seasons, be enjoyed during the succeeding three months; whilst with the *Glycerium*, the inflorescence often only just makes its appearance as bad weather sets in, so that its beautiful plumes are scarcely developed from the leaf-sheaths before they become weather-beaten and disfigured.—"Botanical Magazine," t. 6232.

Spiræa Thunbergiana.—This is an elegant small white-flowered Japanese shrub, and is known in some gardens on the Continent under the name of *S. crenata*. It is a most precious plant, either grown as a hardy shrub in sheltered positions, or for forcing the flowers, being very thickly produced among the small, lance-shaped, fresh green leaves, forming perfect wreaths of star-like flowers, which exhale a delicate spring-like perfume.—"Revue de l'Horticulture Belge," vol. ii, p. 5.

Early Peas and Cherries.—We have been gathering Peas, consisting of Little Gem and Laxton's Unique, ever since the 7th of May. No vegetable is appreciated more than good home-grown green Peas, and, with a little trouble, which they amply repay, they may be had early, late, and in mid season. I used to say that if I were fortunate enough to get charge of cold lean-to houses I would grow Peas and Cherries. I have had my wish gratified. I have just now, although the houses have not been finished two years, ripe Cherries, large in size and fine in flavour. The Cherry trees occupy the back wall, and in front I have a stage, about 2 ft. from the glass. On the 27th of December I got as many boxes, 6 in. deep, 3 ft. long, and 11 in. wide, as made one row about 60 ft. in length. These I filled with good turfy loam and sowed the Peas thinly, one row in the middle of each box. They came up well and grew rapidly; when 6 in. high I stuck them with short bushy twigs. Here they remained until the 4th of April, when they began to bloom. Wishing to place bedding plants in the house to harden I removed them outside, and placed them close to the wall on the south side of an early Peach-house. Here, as I have already stated, I gathered Peas on the 7th of May, and very many since that date; in fact, for three successive days, beginning 31st May, we gathered Peas each day. Just now (on the 4th of June), owing to the hot sun beginning to injure them, they were placed on the north side of the Peach-house, where beautiful fresh pods have been produced. I may be told that there are plenty of Peas outside now; perhaps so, but only in the sunny south, not in Lincolnshire. I may add that last year I gathered Ringleader outside on the 29th of May, but this season my early Peas (sown in November) will not be in for ten days, except The Shah, from which I expect to gather pods this week.—R. GILBERT, *Burghley*.

Fruit Trees in Orchard Houses.—During this season of the year there is plenty of work in orchard houses; the trees should be syringed morning and evening plentifully, and freely watered—a healthy free-growing plant will take up a considerable quantity. The trees should also be surface-dressed. I have found malt-dust mixed with sewage excellent for the purpose, but it must be prepared a month before it is used, and after the water has been added to the dust the heap should be spread out about 1 ft. in depth; do not buy the malt germs, but the dust; maltmakers will know what is wanted. Thinning the fruit must now be commenced, leaving that at the base of a shoot; thin out isolated fruits and those on leafless shoots; but as in unheated houses the stones are not yet formed, the present thinning must not be final; pinch ill-regulated shoots, and put sticks to pyramidal trees that are not straight. As the Peach has a tendency to grow into a standard, all the top shoots of pyramids must be pinched; as a general rule, leave about five leaves; ventilate abundantly. Apricots may now be placed out-of-doors for a succession; in southern districts they will ripen well in the open air. Plums and Pears may also be set outside to leave room for the Peaches and Nectarines. Look closely after the brown aphid; Quassia chips, 4 oz. to the gallon of water and 4 oz. of soft soap added when applied, will keep the trees free from this pest; wash the under surface of the leaves thoroughly.—R.

Does the Phylloxera attack Roots of other Plants besides those of the Vine?—I find in Thomson's "Culture of Fruit under Glass" that numerous experiments have been made to ascertain if the Phylloxera of the Vine would attack or live on the roots of other fruit trees by planting them amongst the roots of Vines infested with that pest, the result being that it was found to attack those of the Vine only; nevertheless, it strikes me that I have read in some of the English gardening papers of instances of its attacking other plants beside the Vine, and I am anxious to know whether or not that is the case. Besides being used for wine making, Grapes here form the principal article of food for the working classes during four or five months of the year; they can be bought for something less than 1d. per lb., and some varieties grown here are equal in flavour, but not in appearance, to the best English hot-house Grapes. Therefore, the Turks have become very much afraid of introducing the Phylloxera to their vineyards, and the Government intend prohibiting the importation not only of fruit trees and Vines, but also of all sorts of plants, which is rather a serious matter in this country for amateurs who grow Orchids and all sorts of stove and other plants. Such a prohibition would injure English nurserymen; therefore, I wish to use my influence with the Turkish Agricultural Society to restrict the prohibition to fruit trees alone, and Vines, of course. Let me hope that some of your readers may be able to throw some light on the subject.—WILLIAM ROSS, *Constantinople*.

Hard Rusty Strawberries.—I have been unsuccessful with Strawberries in pots this season, owing to the fruit becoming hard and rusty. Having paid special attention to the watering and general cultivation I shall be obliged if any of your correspondents will explain what is the probable cause of failure.—F. F.

NOTES OF THE WEEK.

— To Mr. Noble, of Sanningdale, we are indebted for blooms of the handsome and hardy Californian *Rhododendron* (*R. californicum*), a species too little grown. It is very hardy, and the growth does not perish from cold in spring. The delicate rose-lilac flowers and rose-coloured buds are very ornamental.

— SOME out-of-door Strawberries have come to the London market from Devonshire, but they are very poor in quality. The Strawberry season will probably be more than a fortnight later than in 1875.

— We in England never find the Pansy and hybrid Violas, as they are called, refuse to thrive, yet it would appear we have no such beauty to show as may be seen in Scotland, where the climate suits them better. Thirty thousand plants of hybrid Violas and Pansies are now growing in the flower garden at Eglinton Castle.

— It would be difficult to add a charm to the common Hawthorn; the weeping variety is very beautiful just now, and well deserves a place among flowering trees. There is a young specimen of it in Hyde Park, near the Corner. Like most weeping trees, however, its highest beauty of form will not be seen till the specimen is old.

— BROCCOLIES, weighing from 14 lb. to 15 lb. per head, have been sent to Covent Garden during the last few days from Mitchell's market garden at Enfield. Not a plant of the crop of which these formed a part was lost during the past severe winter.

— THE effect of the Great Cow Parsnip (*Heracleum giganteum*) on the islands in the Regent's Park ornamental water is very fine now. This plant, however, should only be introduced to cultivated grounds or even woods with due caution, as it spreads so rapidly and is so vigorous in growth. It is best where its effect may be seen in the distance, and where it may do no harm by spreading.

— IN a letter from New York, one of our correspondents writes—"The time has again arrived when we must witness the destruction of our garden crops by the Colorado beetle. Egg Plants put out in the beginning of last month are already ruined, and Potatoes and Tomatoes are also being destroyed by the same irrepressible pest. What is to be done? Can no one find a remedy?"

— We notice that the specimens of Asparagus which are said to be the finest produced near Paris, belong to the variety *Rose Hative*. Now that many of our cultivators recognise Conover's Colossal to be a distinct variety, it might be well to give a fair trial to this French kind.

— LORD KIMBERLEY, who is spending the Whitsuntide holidays at Falmouth among his tenantry, will shortly present a park to the town. It is being very tastefully laid out, and will, according to the "Times," be formally handed over by his lordship in the course of a few months.

— ONE of the handsomest plants that for a long time have been seen in the flower market in Covent Garden is the old *Phyllocactus Ackermannii*, now seldom seen, but once popular in greenhouses. These are about three years old, scarcely 1 ft. high, and bear from two to six splendid blooms. They are grown by Mr. Pattick, of Acton.

— We have received from the Lawson Company some trusses of a new race of *Rhododendrons*, which are likely to be an important gain for our garden. They are raised from *Rhododendron Aucklandi* crossed with *R. Thomsoni* and *Everestianum*. They are remarkable for unusual size of bloom, with very delicate and distinct markings, and we hope to figure some of the more striking varieties in THE GARDEN. They are quite hardy, having stood several years in the Bangholm Nurseries.

— THE major variety of the St. Bruno's Lily, of which a coloured plate was issued in the first number of THE GARDEN this year, now shows a charming and extraordinary peculiarity in sending up large single flowers from the root. These open before the flowers on the spike, and are larger, resembling the snow-white blooms of a *Panoracium*. Generally one solitary bloom of this kind grows on each plant, and it seems as if strange flowers appeared in the bed. We shall, in a short time, publish an engraving of this flower from the pencil of Mr. Burbridge. This peculiarity of the plant makes it all the more valuable, and points to it as distinct from the ordinary type of St. Bruno's Lily. It may be seen in flower at the Wellington Nurseries, St. John's Wood.

— A MEETING was held at South Kensington, on Friday, for the purpose of considering what steps should be taken to commemorate the services to horticulture of the late Louis van Houtte. It was resolved to open a subscription list for the purpose of founding a prize

to be called the Van Houtte Prize (probably a medal), to be awarded at the Quinquennial Exhibition at Ghent. A committee was formed, with power to add to their number, for the purpose of giving effect to the resolution, and though the number present was but small, about fifty guineas were at once subscribed. From the numerous letters received, it is obvious that the movement has the hearty support of the leading nurserymen of the country. Mr. Harry Veitch has been appointed secretary, to whom subscriptions should be forwarded.

— CAULIFLOWERS now come in abundance, and large and well-formed, from the Paris market gardens to the London market. English Cauliflowers are also getting plentiful.

— THAT elegant little Grass *Agrostis pulchella* forms a graceful pot-plant at this season, and is grown for the London market—the best plants being autumn sown.

— THE fine Ramanas Rose (*Rosa rugosa alba*) is now in blossom at the Hale Farm Nurseries, and very beautiful it is. The little Pyrenean Rose is also in flower. We hope to see both plants at home in many gardens soon.

— THE Rocky Mountain Yellow Columbine (*Aquilegia chrysantha*) does not come true from seed here, but gives birth to a beautiful race which seem intermediate between it and *A. corulea*, and which are very charming plants. A *chrysantha* is a better perennial than most *Columbines* both in this country and its native one.

— A VERY Double Pansy "large and full," as the catalogues say, is a novelty, and a far finer flower than one would expect, though not so showy or beautiful as a good single flower. The one we allude to is called Lord Waveney, and is now in bloom in the Hale Farm Nurseries.

— THE true large *Iris longipetala*, now in bloom, is a fine species with the falls of the flower beautifully netted with violet, so as to remind one of the blossoms of the *Zygopetalum Mackayi*. Distinct *Irises* are very desirable, but there are a great many intermediate forms which are not worthy of cultivation. There is a curious and fine hybrid in flower at Ware's, between *I. iberica* and apparently one of the dark German *Irises*.

Gardens in New Guinea.—Some notion of the luxuriance of the vegetation of the Macley Coast may be got from the following:—So thickly is the coast of Astrolabe Gulf covered with vegetation that houses are almost invisible, the only signs of habitation being perhaps columns of smoke. If, however, more careful observation be made, separate groups of Cocoa-nut Palms will be noticed. The plantations or gardens of the natives are seldom laid out near their huts, but, for the sake of security, are hidden in the jungle. A clearing is made by cutting down the underwood, and, after it has been dried in the sun, it is set on fire. The space thus prepared is then surrounded by a hedge, consisting of two rows of a kind of Sugar-cane (*Saccharum spontaneum*), which soon takes root, the opposite stems being fastened together with Lianas, and the space between the rows filled with rough-hewn logs. In less than a month's time a new plantation is put in full order and planted with Bananas, Sugar-cane, and the *Colocasia* and *Dioscorea*. The tools which are used for this purpose are very simple, being the *udja*, a strong stick about two yards in length, and sharpened at one end—the implement of the men; and the *udja-sab*, which is used by the women, a kind of small spade. The Papuans have throughout the year a rotation of fruit and vegetables. Every day the women go forth to fetch from the plantations what is necessary for the same evening and the following morning. The coast people have the most property in cultivated land.

Character in Gardens.—Were each to consult his own taste in the garden, instead of imitating his neighbour, every garden, large or small, would assume a character of its own. This would give variety and the sense of novelty or individuality to each garden, which could hardly fail to enhance the pleasure to be had from it. The garden is the very place in which to ride a hobby. It is much safer to do so than in any other occupation—for horticultural hobbies are always innocent, harmless, and, relatively to others, cheap. One lady, for instance, delights in Lilies—let her garden, therefore, be mainly a garden of Lilies. Another cares for nothing but Roses—what more charming than a garden of Roses! Another rejoices in spring flowers above all others—let hers be a spring garden. And so with all other plants, trees, shrubs, and flowers. Each man and woman's garden should mirror forth, as it were, the individual taste. By amateurs selecting to grow most of those they like, room enough would be found to do their favourites justice.—D. T. FISKE.

THE FLOWER GARDEN.

WATER-PLANTS IN THE WILD GARDEN.

WATER-PLANTS of northern and temperate regions, associated with those of our own country, add much beauty to a garden if well selected and well grown. A great deal of beauty may be added to the margins, and here and there to the surface, of ornamental water, by the use of a good collection of hardy aquatics arranged with some taste; but, so far as I have seen, this has not yet been fairly attempted by any designer of a garden or piece of water. Usually we see the same monotonous vegetation all round the margin, if the soil be rich; in some cases, where the bottom is of gravel, there is little or no vegetation, but an unbroken ugly line of washed earth between wind and water. In others, water-plants accumulate till they are a nuisance and an eyesore—I do not mean the submerged plants like *Anacharis*, but such as the Water Lilies, when they get matted together. A well-developed plant or group of plants of the queenly Water Lily, with its large leaves and noble

flowers, is an object not surpassed by any other in our gardens; but when it increases and runs over the whole or a large part of a piece of water—thickening together and being in consequence weakened—and water fowl cannot make their way through it, then even the queen of British water-plants loses its charms. No garden water, however, should be without a few fine plants or groups of the Water Lily. Where the bottom does not allow of the free development of the plant, scrapings or earth might be accumulated in the spot where it was desired to encourage the growth of the *Nymphaea*. Thus arranged, it would not spread too much. But it is not difficult to prevent the plant from spreading; indeed we have known isolated plants and groups of it remain of almost the same size for years.

The Yellow Water Lily, *Nuphar lutea*, though not so beautiful as the preceding, is well worthy of a place; and also the little *N. pumila*, a variety or sub-species found in the lakes of the north of Scotland. Then there is the fine and large *N. advena*, a native of America, which pushes its leaves boldly above the water, and is very vigorous in habit. It is very plentiful in the Manchester Botanic Garden, and will be found to some extent in most gardens of the same kind. The American White Water Lily (*Nymphaea odorata*) is a noble species which would prove quite hardy in Britain. It is a pity this noble aquatic plant is not more frequently seen, as it is quite as fine as our own Water Lily. Rose-coloured varieties are spoken of, but I have never seen them.

One of the prettiest effects I have ever observed was afforded by a sheet of *Villarsia nymphaeoides* belting round the margin of a lake near a woody recess, and before it, more towards the deep water, a fine group of Water Lilies. The beauty of this *Villarsia* is very insufficiently developed in garden waters. It is a charming little water-plant, with its *Nymphaea*-like leaves and numerous golden-yellow flowers, which furnish a beautiful effect on fine days, under a bright sun. It is not very commonly distributed as a native plant, though, where found, generally very plentiful, and not difficult to obtain in gardens where aquatics are grown.

Not rare—growing, in fact, in nearly all districts of Britain—but exquisitely beautiful and singular, is the Buckbeak or Marsh Trefoil (*Menyanthes trifoliata*), with its flowers elegantly and deeply fringed on the inside with white fila-

ments, and the round unopened buds blushing on the top with a rosy-red like that of an Apple-blossom. In early summer, when seen trailing on the soft ground near the margin of a stream, this plant has more charms for me than any other marsh plant. It will grow in a bog or any moist place, or by the margin of any water. Though a rather common native plant, it is not half sufficiently grown in garden waters. For grace and singularity combined, no water-plant can well surpass *Equisetum Telmateia*, which, in deep soil, in shady and sheltered places near water, often grows several feet high, the long, close-set, slender branches depending from each whorl in a singularly graceful manner. It grows in many parts of England, but does not penetrate far into Scotland. It will grow on the margins of lakes and streams, especially among water-side bushes, or in boggy spots in the shade.

For a bold and picturesque plant on the margin of water, nothing equals the great Water Dock (*Rumex Hydrolapathum*), which is rather generally dispersed over the British Isles; it has leaves quite sub-tropical in aspect and size, becoming of a lurid red in the autumn. It forms a grand mass of foliage on rich muddy banks, and, unlike many water-plants, has the good quality of not spreading too much. It is used with good effect on the margins of the islands in Victoria Park. The Cat's-tail (*Typha*) must not be omitted, but it should not be allowed too much liberty. The narrow-leaved one (*T. angustifolia*) is more graceful than the common one (*T. latifolia*). *Carex pendula* is excellent for the margins of water, its elegant drooping spikes being quite distinct in their way. It is rather common in England, more so than *Carex pseudo-cyperus*, which grows well in a foot or two of water or on the margin of a muddy pond. *Carex paniculata* forms a strong and thick stem, sometimes 3 ft. or 4 ft. high, somewhat like a tree Fern, and with luxuriant masses of drooping leaves, and on that account is transferred to moist places in gardens, and cultivated by some, though generally these large specimens are difficult to remove and soon perish. *Scirpus lacustris* (the Bulrush) is too distinct a plant to be omitted, as its stems, sometimes attaining a height of more than 7 ft. and even 8 ft., look very imposing; and *Cyperus longus* is also a desirable plant, reminding one

The White Water Lily.

of the aspect of the Papyrus when in flower. It is found in some of the southern counties of England. *Poa aquatica* might also be used. *Cladium Mariscus* is another distinct and rather scarce British aquatic which is worth a place.

If one chose to enumerate the plants that grow in British and European waters, a very long list might be made, but the enumeration and recommendation of those which possess no distinct character or no beauty of flower would be useless, for it is only by a judicious selection of the very best kinds that gardening of this description can give satisfaction; therefore, omitting a host of inconspicuous water-weeds, we will endeavour to indicate others of real worth.

Those who have seen the flowering Rush (*Butomus umbellatus*) in blossom, are not likely to omit it from a collection of water-plants, as it is conspicuous and distinct. It is a native of the greater part of Europe and Russian Asia, and is dispersed over the central and southern parts of England and Ireland. Plant it not far from the margin, as it likes rich muddy soil. The common *Scitarraria*, very frequent in England and Ireland, but not in Scotland, might be associated with this; but there is a very much finer double exotic kind to be had here and there, which is really a handsome plant, its flowers being white, and resembling, but larger than, those of the old

white Double Rocket. This used to be grown in abundance in the pleasure gardens at Rye House, Broxbourne, where it filled a sort of oblong basin, or wide ditch, and looked quite attractive when in flower. It has the peculiarity of forming large egg-shaped tubers, or rather receptacles of farina, and in searching for these, ducks destroyed the plants occasionally. This makes me suspect that it might prove a useful plant for feeding wild fowl, and that it might be worthy of trial in that way. No native water-plant that I am acquainted with has anything like such a store of farina as is laid up in the tubers of this plant. *Calla palustris* is a beautiful bog-plant, and I know nothing that produces a more pleasing effect over rich, soft, boggy ground. It will also grow by the side of water. *Calla æthiopica*, the well-known and beautiful Lily of the Nile, is hardy enough in some places if planted rather deep, and in nearly all it may be placed out for the summer; but except in quiet waters, in the south of England and Ireland, I doubt if it would make any progress. However, as it is a plant so generally cultivated, it may be tried without loss in favourable positions. The Pine-like Water Soldier (*Stratiotes aloides*) is so distinct that it is worthy of a place; there used to be a pond quite full of this at Tooting, and it is common in the fens. The tufted Loose-strife (*Lysimachia thyriflora*) flourishes on wet banks and ditches, and in a foot or two of water. It is curiously beautiful when in flower; rather scarce as a British plant, but found in the north of England and in Scotland. *Pontederia cordata* is a stout, firm-rooting, and perfectly hardy water-herb, with erect and distinct habit, and blue flowers, not difficult to obtain from botanic garden or nursery. The common *Acorus*, or Sweet-flag, will be associated with the Water Iris (*I. Pseud-acorus*), the rather ornamental Water Plantain (*Alisma Plantago*), and the pretty *Alisma ranunculoides*, if it can be procured; it is not nearly so common as the Water Plantain. The pretty and interesting little Star Damasonium of the southern and eastern counties of England is very interesting, but, being an annual, is not to be recommended to any but those who desire to make a full collection, and who could and would provide a special spot for the more minute and delicate kinds. In such a spot, or even in the basin of a fountain, where they should be safely watched from being choked by larger weeds, the very tiny and pretty yellow Water Lily (*Nuphar Kalmiana*), the little pale blue Water Lobelia (*L. Dortmanni*), and not a few others, might be grown. This Lobelia does not seem to thrive well away from the shallow parts of the northern lakes, getting choked by the numerous water-weeds. *Aponogeton distachyon* is a native of the Cape of Good Hope, a singularly pretty plant, which is nearly hardy enough for our climate generally, and, from its sweetness and curious beauty, a most desirable plant to cultivate. It frequently succeeds in the south in water not choked by weeds or foulness, and wherever there are springs that tend to keep the water a little warmer than usual it seems to thrive in any part of the country. It should be planted in a clean spot and in good soil. The Water Ranunculuses, which sheet over our pools in spring and early summer with such silvery beauty, are not worth an attempt at cultivation, so rambling are they; and the same applies to not a few other things of interest. *Orontium aquaticum* is a scarce and handsome aquatic for a choice collection, and as beautiful as any is the Water Violet (*Hottonia palustris*). It occurs most frequently in the eastern and central districts of England and Ireland. The best example of it that I have seen was on an expanse of soft mud near Lea Bridge, in Essex, where it covered the surface with a sheet of dark fresh green, and must have looked better in that position than when in water, though doubtless the place was occasionally flooded. *Polygonum amphibium* and *P. Hydropiper* frequently flower prettily by the sides of streams and pools, while the Marsh Marigold (*Caltha palustris*), and its varieties will burnish the margins with a glory of colour which no exotic flower could surpass. A suitable companion for this *Caltha* is the very large and showy *Ranunculus Lingua*, which grows in rich ground to a height of 3 ft. or more. *Lythrum roseum superbum*, a beautifully coloured variety of the common purple Loose-strife, and *Epilobium hirsutum*, are two large and handsome plants for the water-side.

When to the above, and many others, are added the various noble Ferns of America and Europe that thrive by the water-side (the *Osmundas*, for example), a beautiful garden is the result. If with this water-garden we combine the wild garden of land—herbaceous plants, trailers, &c.—some of the loveliest effects possible in gardens will be produced. The margins of lakes and streams are happily not upturned by the spade in winter; and hereabouts, just away from the water-line, almost any vigorous and really hardy flower of the thousands now in our gardens may be grown and will afterwards take care of itself. The Globe-flowers alone would form beautiful effects

The Yellow Water Lily.

in such positions, and would endure as long as the Grass. Near the various Irises that love the water-side might be planted—those that thrive in moist ground—and they are many, including the most beautiful kinds. Among recently-introduced plants we think the singular Californian *Saxifraga peltata* is likely to prove a noble one for the water-side, its natural habitat being beside mountain water-courses, dry in the autumn when it is at rest; both flowers and foliage are effective, and the growth very vigorous when in moist ground. It would require a very long list to enumerate all the plants that would grow near the margins of water, and, apart from

The Great Water Dock.

the aquatics proper; but enough has been said, we hope, to prove that, given a strip of ground beside a stream or lake, a garden of the most delightful kind could be formed. The juxtaposition of plants inhabiting different situations—water-plants, water-side plants, and land-plants thriving in moist ground—would present what would, in many cases, be so undesirable—a general admixture of the whole. Two distinct classes of effects would be obtained, the beauty of the more delicate flowers seen close at hand, and that of the more conspicuous kinds in the distance or from the other side of the water of a stream or lakelet.

W. R.

Clapham's Strain of Mimulus.—I have had a quantity of these beautiful Mimulus in flower for some time, and they flowers are so large and so richly coloured as to make them scarcely inferior to the *Calceolaria* in richness and beauty. The flowers resemble those of a single *Petunia* in size; some have white, some orange, and some pale yellow grounds, and all are richly blotched. The seed was sown in a pan late in October, and about Christmas the strongest plants were pricked out into small pots, making a couple of batches, the smallest being kept for planting out into the open ground at the end of May. The first lot next got a shift into 48-sized pots, and finally into 24-sized pots, in which they flowered in perfection. As soon as the weather gets at all warm they should be placed in a cool frame, facing the north, and when in flower should be kept in a cool house, where they will bloom abundantly for a long time. Watering must be attended to, for if allowed to get dry at the root, a check will be the result.—D.

New Hybrid Perpetual Rose—Duke of Connaught.—This is an English seedling, raised in the old nurseries at Cheshunt, and exhibited last summer for the first time, when it received much attention on account of its full form and brilliant colour. It is a seedling from Madame Victor Verdier, and somewhat resembles that variety in foliage and general habit; its colour, however, is the nearest approach to scarlet of any variety yet raised. This season Messrs. Paul and Son have exhibited plants of it in flower, and also out blooms, both at the Regent's Park and South Kensington Exhibitions, and on both occasions it was deservedly awarded first-class certificates. In the last number of the "Floral Magazine," there is a coloured representation of it.

Daisies.—As these are now very properly admitted to the prominent place to which they have long been entitled, it may be interesting to know that I met with the largest Daisies I ever saw, and of which there were a profusion flowering in autumn, near Mentone, on the road to Nice. Are the little flowerets which bloom all round the parent white Daisy so often seen in cottage gardens, ever found round the red double one? This inquiry has hitherto invariably been met by a negative; also, does the white Daisy, when transplanted and become double, produce those flowerets commonly known as Hen-and-Chickens? And, lastly, is it an invariable result of transplanting wild Daisies that they become double? as such a result, though very convenient and desirable in some situations, is the reverse in others, where a border of single Daisies would be preferable. Is there therefore no means of controlling the growth of this flower? Those hitherto transplanted by me have all become double in a certain time, but none have produced Hen-and-Chickens.—B. [The peculiar form of inflorescence known as Hen-and-Chickens, is limited to the variety so-called exclusively. The wild Daisy has never become double with me, but it is not improbable that plants of it growing in good garden soil may at times produce a superabundance of petals, but not sufficient to entitle them to be called double. Seed saved from such plants might eventually produce semi-double flowers, but it should be remembered that Daisies thus produced under cultivation and selection, would be no longer wild but garden varieties. As double Daisies seed less freely than single ones, that circumstance should be rather a recommendation for garden use than otherwise, inasmuch as the wild single Daisy, however pretty, is after all only a weed in gardens and soon becomes a nuisance; besides, in no case does it look more beautiful than when seen growing in its native pastures.—A. D.]

Clematises for the Wild Garden.—Mr. Jackman has given us the following list of the kinds of Clematis most likely to thrive in the wild garden—that is to say, the strongest growers, and those most likely to take care of themselves. They consist of the white, Wood-anemone-like *C. montana*; Anemone-like, delicate mauve-purple; Jay Rosamond, bluish white with a somewhat indistinct wine-red bar up the centre of each sepal, the stamens very prominent and distinct; John Murray, a remarkably free-growing and free-blooming variety, flowers eight-sepaled, of a deep purplish mauve, becoming reddish towards the base of the bar; Lord Derby, previously described in THE GARDEN; Lady Londesborough, silver grey, with pale bar; Patens (azurea grandiflora), delicate mauve-lilac; Sir Garnet Woseley, already described in our columns; Standish, light mauve-purple; Stella, flowers light violet or deep mauve, with a distinct bar in the centre of each sepal of a deep reddish plum colour; The Queen, delicate lavender or mauve, having much the appearance of moderate-sized blossoms of *C. lanuginosa*; Vesta, and Countess of Lovelace, described at p. 408; Lucie Lemoine, white rosette-formed, with pale yellow anthers; Gem, deep lavender-blue; Lanuginosa candida, tinted greyish white; William Kennett, deep lavender; Crispa (Shillingii), pinkish white, bell-shaped; Henderson, bluish purple, bell-shaped; Lady Bovill, greyish blue, cupped; Mrs. James Bateman, pale lavender; Thomas Moore, violet, with white stamens, Passiflora-like;

Viticella major, reddish plum colour; *Viticella rubra grandiflora* bright claret-red; Alexandra, pale reddish violet; Flammula, white, sweet-scented, small-flowered; Jackmanni, intense violet-purple; Lady Strafford de Redcliffe, a novel variety of the mixed type, somewhat of the character of the Jackmanni group, flowers eight-sepaled, measuring fully 6 in. across, of a delicate mauve colour with a greenish tint in the centre bar or rib, the anthers chocolate red, soon becoming greyish; Prince of Wales, deep purple; Rubella, rich claret-purple; and Velutina purpurea, blackish mulberry.

The Lacrosse Flower Vase.—This vase is a recently novelty invented and registered by Messrs. Whyte & Sons, glass manufacturers, Dublin, a firm well-known as the inventors of the celebrated Lady Spencer Flower-stand. The principal advantage claimed for this novelty, says the "Gardeners' Record," is that it cannot be upset, for the bottom portion of the vase is a solid ball glass, which renders it so steady that it is not, like the ordinary form of finger or flower-glass, liable to be overturned on the table by a slight shake or touch. It is so constructed that even when purposely turned over the upper portion of the glass falls so lightly on the table that it did not break. The great objection to small glasses of this description is their tendency to overbalance themselves when flowers are arranged in them.

Tree Ferns Hardy in Arran.—A communication, relating to this subject, was lately made by the Rev. D. Landsborough to the Botanical Society of Edinburgh. "On both sides of a house at Corrie, on the east side of the island," he says, "I noticed remarkably sheltered corners; in one of these, in 1867, I placed a small plant of the great Australian Tree Fern, *Dicksonia antarctica*, and in the other a similar plant of that most beautiful of all Tree Ferns, the silvered *Cyathea dealbata*. The *Cyathea* grew beautifully during the summer, stood the winter perfectly, but was afterwards stolen. The *Dicksonia* is now provided with nine fronds, of which the largest is 4 ft. in length by 22 in. in breadth; it makes two growths in the year, sending out fronds in April and May, and again others in September and October. It is of course an evergreen, and looks better in winter than in summer, as in winter all the fronds are of full size. It has not yet begun to form a stem, but I understand that even in its native clime it does not begin to do so till it has grown for about a dozen years. I may add, that it is somewhat doubtful if it will continue to thrive as well as hitherto, for within the few last weeks a magnificent Strawberry tree, *Arbutus Unedo*, which sheltered it from sun and wind, has been blown down."

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Striking Pinks in Water.—It has recently been found that Pink pipings stand freely and up in small bundles and placed in water. When the roots are well developed, the pipings should be pricked out into a frame or under hand-lights until they are strong enough for moving into pots or borders.—A. D.

Tree and other Peonies.—Peonies of all kinds, both herbaceous and Montan, are now very beautiful in London gardens. At Hampton Court they are just now gorgeous, both in beds and borders, margined with London Pride (*Saxifraga umbrosa*), a most effective arrangement. Here also P. Montan, a delicious rose-scented variety of a soft bluish tint, is very attractive.—B.

Alliums.—Dr. Regel has lately published an extensive work on this genus, which forms a volume of more than 250 pages. There are no fewer than 263 species of Allium. The greater number belong to the region of the Mediterranean, to the East and Japan, and many of them are of horticultural interest.

The Great Double Buttercup.—This is now so splendid in London gardens that we again call the attention to it, its flowers being in some cases as large as those of a Persian *Ranunculus*, beautifully formed, very double, and like burnt gold. It is known by various names in gardens such as *Ranunculus speciosus* fl.-pl., *R. bullatus* fl.-pl., *R. gouani* fl.-pl., but the best garden name for it is that which heads this note.

A Graceful Mixture.—I noticed the other day some young stems of the Wood Horsetail (*Equisetum*) coming up through a large tuft of *Stellaria* in flower, the *Equisetum* resembling delicate miniature weeping trees growing over the snowy mass of bloom. Such combinations suggest what artistic gardening may come to when we really use tastefully the mass of material at our disposal.—V.

Flowers Grown in Churchyards.—As the custom of decorating the interiors of churches is becoming more common, we would suggest, at least in the country, for each church to grow its own flowers, and thus accomplish two ends—decorating both the church and churchyard. In many country and suburban churchyards there is plenty of room in which even the choicest flowers might be grown in quantity.

New Poppy.—Mr. Thompson's new Poppy (*Panaver umbrosum*) has just opened its first flower here and is singularly beautiful; the flower is about the size of that of *P. Rhoeas*, dark red in colour with large black blotches in each petal both inside and out, and inside they (the blotches) are edged with a peculiarly pretty tint of grey. The leaves and habit are very like those of *P. Rhoeas*, and I have no doubt it is an annual.—J. G. WILSON, *Aldborough, Norwich*.

Sundews.—I have been reading in THE GARDEN an account of some experiments that were made with the common Sundew (*Drosera rotundifolia*). I should be pleased to supply any of your correspondents with specimens of that plant, having plenty of it near me.—JAS. GIBBS, *Cheriton Park, East Grinstead*.

THE DANDELION.

WHETHER we consider the Lilies of the field or not, it is strange how few of us consider the early Dandelion by the way-side. And yet it is the very foot-print of spring herself, and whenever we see the Dandelion we know that she has passed that way. But we waste none of our oestacis on the blossom. It has not the spicy savour of the Mayflower, nor the rich shadow of the Violet, nor the delicate fibre of the Anemone. We do not pluck it for our vases; we should laugh at ourselves if we wore it for a breast-knot; yet, after all, find us a lovelier diadem than these wide open golden stars would make below the dark braid. Examine it well, and see if more filmy beauty can be found than that of each one of the tiny flowerets; and for its purposes, coming to brighten a dark and weary land still sad with the chill of departing winter, is not the splendour of its tint a better thing than all the purples that, a month later, when the scene is sunny and serene and secure, come and line the brook's side, and embroider the mill? But if we elders do not appreciate it, children do. That child has never yet been born who did not love the Dandelion. To children even the Rose is less welcome, and Orange and Jasmine could give them no blossom half so choice. Its colour, its wildness, its abundance, its little worth in our eyes, are all dear to them. When they see it they know the long out-door freedom of summer pleasures has begun. They hail it with acclamation, they carry it in their little warm hands till it wits, they make curls from its long plant stems to hang around their ears, they stick it in old bottles and broken pitchers, they set it out rootless but blossoming in their miraculous flower-beds, and they tell their fortunes by its blowing dust when it has gone to seed. It is as much their friend and the companion of their play, as the household dog is. The children, too, are right. It is we whose eyes are shut, we do not see the perfect circle, the multitudinous petals fringed fine as the Gentian's, the dusty delicacy of the tissue. It is so common that we give all this loveliness nothing but contempt, and we never stop to think of the exquisite work shut up in its corolla, with the only post who to our knowledge, has ever sung its praises:—

“Gold such as thine ne'er drew the Spanish proverb
Through the primal hush of Indian seas,
Nor wrinkled the lean brow
Of age to rob the lover's heart of ease,
’Tis the Spring's largess, which she scatters now
To rich and poor alike, with lavish hand,
Though most hearts never understand,
To take it at God's value, but pass by
The offered wealth with unrequited eye.”

De Candolle on the so-called Carnivorous Plants.—M. Casimir De Candolle has lately published a memoir on the structure and movements of the leaves of *Venus' Fly-trap* (*Dionæa muscipula*), in which, after describing the structure of the plant, he arrives at the following conclusions:—1. That the animal matters absorbed by the leaves are not directly made use of by them and are not necessary to the development of the *Dionæa*. 2. That the marginal appendages are distinct from the rest of the leaf, and hence the reason why their movements do not take place simultaneously with those of the two halves of the blade of the leaf. 3. That the star-shaped hairs, like the glands, are epidermal productions only, while the parenchyma of the leaf has a share in the development of the sensitive hairs. 4. That stomata exist on both sides of the wing petiole, while on the blade of the leaf they occur on the lower surface only. 5. That the anatomical structure, like the development of the different parts of the leaf, favours the hypothesis that the movements of the two halves of the leaf result from variations in the degree of turgescence of the cellular portion of the upper surface of the leaf. 6. That the sensitive hairs are conductors, which permit the impressions they receive to act directly on the cellular tissue of the leaf beneath the epidermis.

Tropical Fruits in Egyptian Gardens.—According to M. Delevalerie, writing in the “Bulletin Sociéti d'Acclimatation” the Rose Apple ripens its fruit perfectly in the gardens of the Khedive at Ghezirah. It bore fruit for the first time in Egypt in 1868, and there are trees now over 25 ft. in height. The Mango fruits abundantly in the gardens of Cairo, and the fruit is of delicious flavour. The largest trees are about 30 ft. high. Several varieties of Papaw flourish at Alexandria and Cairo. The Sweet-sop is cultivated in almost every garden, and the Arabs call it the Cream-Fruit. Other trees and shrubs grown for their fruits are *Eglo Marmelos*, *Eriobotrya japonica*, *Eugenia australis*, *Musa siensis*, *Persea gratissima*, the Guavas, and the Tamarind. These are mostly of recent introduction; various other tropical fruits have been grown for a long period in Egypt.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE majority of spring-flowering bulbs have passed away, and leave considerable blanks, except in the wild garden, where they are not missed. The noble summer bulbs, mostly Lilies, have not yet opened, but there is a magnificent glow of colour in well-stocked gardens. Many showy plants are now in blossom, none more important than the various Thrifts, best of all being the pure rose-coloured and white forms of the native species. The variegated Irises are now very showy and beautiful; so, too, are the Peonies, though less attractive than usual owing to the severe spring. Many Saxifrages show their myriads of starry blossoms, and the *Pyrethrums* (double and single varieties of *P. roseum*) are effective where well chosen and well grown. Among these, however, there are too many intermediate forms which tend to produce monotony. The aim of nurserymen and hybridisers must for the future be the weeding out of those too numerous, and the cultivation of really distinct ones. It is hard to say that any form of Iris, or Daffodil, or Lupine is not valuable, as these are certainly all beautiful flowers; but the fact is a number of similar forms slightly varying tend to weaken the effect of the distinct ones, and make the task of selection more difficult for the gardening public, and, therefore, are injurious to horticulture. It is common at present, for example, to see masses of seedling and hybrid Irises in gardens and nurseries without any distinct character, and no striking beauty of colour, while the really stately rich-coloured and distinct kinds are far too scarce. The double Marigold is very fine just now, its colour being a good successor to the handsome orange blooms of the Japan Globe-flower. The Bohemian Comfrey is one of the handsomest plants of the season, and very fine as a border plant. The smaller *Phloxes* are for the most part past, the family, however, being well represented by *Phlox ovata*, now in full bloom, and about a foot high. Some of the so-called tree *Lupines*, begin to be effective, and we notice some pleasing lilac-coloured forms among them. Nothing can be more lovely than the large delicate rose blossoms of *Geranium cinereum*, rising from very inconspicuous plants. The shrubby sea-green *Veronica pinguifolia* is a very distinct and neat rock or border plant, now in flower. The following are among the plants noted on Monday last:—*Veronica caucasica*, *Silene quadrifida*, *Erigeron Roylei*, *Chrysobactron Hookeri*, *Convolvularia bifolia*, *Dianthus alpinus*, *Aquilegia glandulosa*, *A. olympicum*, *Crepis aurea*, *Geum montanum*, *Geranium cinereum*, *Edraianthus Pumilio*, *Erodium macradenium*, *Hedysarum obscurum*, *Ranunculus uriflorus*, *Pisum maritimum*, *Tradescantia virginica*, *Phyteuma orbiculare*, *Crocianella stylosa*, *Erigeron Philadelphicum*, *Veronica saxatilis*, *Viola heterophylla*, *Phlox ovata*, *Allium ciliatum*, *Erodium Manescavi*, *Calendula officinalis*, fl.-pl., *Muscari comosum*, *M. c. monstrosum*, *Iris longipetala*, *Primula luteola*, *Orobanchis aurantiaca*, *Dianthus deltoideus*, *Lychnis Lagasca*, *Rosa pyrenaica*, *Campanula nobilis*, *Veronica pinguifolia*, *Alyssum spinosum*, *Melittis Melissophyllum*, *Linum arboreum*, *L. campanulatum*, *Astragalus monspessulanus*, *Æthionema grandiflorum*, *Lilium colchicum*, *Aster alpinus*, *Lithos corniculatus*, *Symphytum bohemicum*, *Veronica prostrata*, *Rudbeckia Newmanii*, *Scabiosa montana*, *Veronica caucasica*, *Lactuca sonchifolia*, *Hemerocallis japonica*, *H. flava*, and *Aquilegia chrysantha*.

Source of Latakia Tobacco.—Mr. Thiselton Dyer exhibited, at a late meeting of the Linnean Society, specimens of Latakia Tobacco, which has hitherto been considered to be the produce of *Nicotiana rustica*. By soaking under the constituent parts it was found to consist of the upper part, inflorescence, and young capsules of a form of *N. Tabacum*. The peculiar flavour it is suspended for some months.

Asarum canadense as an Aromatic.—The roots of this form an officinal drug, which is in the secondary list of the United States Pharmacopœia, and is known under the popular names of Wild Ginger, Indian Ginger, Colt's-foot root, and Canada Snake root; it is used instead of Ginger by the country people in some parts of New England. On account of its medicinal properties, it has been noticed by American writers on native medicines; but it seems to be little used in regular practice.

Phyllis peruviana.—Dr. Sagot, who has paid much attention to these berry-bearing plants, recommends horticulturists in the south of Europe to cultivate this species, which is one of the best of the genus for flavour and perfume.

Long-flowered Harebell (*Campanula nobilis*).

Yellow Day-lily (*Hemerocallis flava*).

Caucasian Lily (*Lilium monadelphum*).

Tawny Day-lily (*Hemerocallis fulva*).

Virginian Spiderwort (*Tradescantia virginica*).

Feathery Hyacinth (*Muscari comosum*).

Round-headed Phyteuma (*Phyteuma orbiculare*).

Blue Daisy (*Aster alpinus*).

Bell-flowered Flax (*Linum campanulatum*).

Maiden Pink (*Dianthus deltooides*).

Long-styled Crucianella (*Crucianella stylosa*).

Showy Heron's-bill (*Erodium Manescavi*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE AMATEUR'S GARDEN.

BY THOMAS BAINES.

Insect Remedies.—The greatest discouragement which amateurs experience in their first attempts at gardening is the struggle necessary to cope with the numberless insects that make their undesired appearance upon almost every plant in cultivation, indoors and out, and that demand increasing attention to prevent the total destruction, or injury to a serious extent, to whatever they prey upon. One of the first essentials to success in gardening is to fully realise the fact that the most assiduous and continuous warfare must be waged against the different insect-pests which are constantly attacking the greater portion of plants in cultivation, either at the root, the top, or both. Whenever there is any delay in taking means for their destruction, not only are the affected plants sure to be proportionately injured, but the difficulty of extirpation is generally increased to an extent that could not be credited by the uninitiated. This will be easily understood by a little reflection upon the rapidity of increase in most of the insects that are more prevalent in summer. If the few curled leaves on the first shoot or two of a Peach or Cherry tree on the walls, or the young growths of a Rose, be at once effectually syringed or dipped in Tobacco or Quassia water, or dusted with Tobacco powder, the work that afterwards would take hours to accomplish may be completed in a few minutes, with the additional advantage of the plant receiving but little injury, whereas if it be delayed the leaves turn yellow and fall off, the flowers come deformed and useless, and the insects spread all over the tree or bush, entailing immeasurably more difficulty in their removal, and often an amount of injury that extends far beyond the current year; this is especially the case with Peaches and Nectarines. Even should the trees be strong and vigorous, if aphides be allowed to remain undisturbed for a week or two a considerable portion of the leaves get destroyed, the effects of which are the present season's fruit never attains its full size or quality; a weak second growth is made that has not a chance—particularly in districts where this fruit has only just enough time to ripen its wood—of ever getting the fruit-buds matured for another season. I merely instance the above as plants that are especially subject to aphides, and which in any locality rarely pass through a summer without being affected; but there are innumerable subjects in plant life that are scarcely less liable to their attacks. Later on in the season red spider and thrips are sure to make their appearance, and, if not dealt with promptly, will be equally destructive. In the majority of cases, amateurs' gardens are more or less confused, and thus favour the production of these insects to an extent that does not exist in larger gardens, which are more fully exposed to the influence of the winds. This particularly applies to aphides, which usually make their first appearance in the most sheltered spots. Where time is not an object, aphides, thrips, and red spider can be kept under by a diligent use of the syringe and garden engine, and in most cases, so far as out-door plants are concerned, after an application with any of the usual dressings in the spring for the first brood, it is sufficient afterwards to ply the syringe or engine with constant vigour. With plants under glass it is even more necessary to exercise continuous vigilance, for the conditions as to temperature and choice of food that favour the increase of insects are more or less always present throughout the year, and many of the plants are less able to withstand their attacks than those grown in the open air. For aphides and thrips the most usual remedy is fumigation, but Tobacco smoke always leaves a disagreeable smell for some days afterwards, and if the plant-house be in any way connected with the dwelling fumigation is still more objectionable. The necessity for smoking may often be dispensed with if a painful of Tobacco-water be always in readiness, in which any affected plant may be dipped as soon as a trace of insects is discovered; the labour it entails is slight, and the application, if thorough, is generally more effectual than fumigation, as it destroys the eggs as well as the living insects; but whatever means are employed for their destruction, it is necessary that there should be unlimited watchfulness at all times. Of the different pests that harbour in the soil, and that prey upon cultivated plants, slugs are the worst; their ravages are most apparent in such springs as the present, when the weather has been so ungenial that vegetable life makes slow progress, and has not sufficient vigour to withstand the continual onslaught of these slippery marauders. In many places where they are numerous, and means have not been assiduously employed to annihilate them, the first crops of Peas, Lettuces, and Cauliflowers have been completely destroyed, whereas if Cabbage leaves, light boards, or anything of a similar nature had been employed, that would have attracted them either to feed upon or harbour under, and these daily examined, the crops would have escaped. All that is usually recommended as a preventive against slugs in the shape of ashes, lime, soot, chopped straw, chaff, or similar material, to impede their progress can be nothing

more than a temporary measure that does not remove the cause of the evil, the only cure for which is reducing them to the lowest possible numbers. If once slugs be reduced to a small number, and the soil amongst the different growing crops be kept continually stirred—which is necessary both for their general well-being and the destruction of weeds—it will have the effect on the slugs of exposing them and their eggs to their natural enemies—the birds. Amateurs in their first attempts at gardening are apt to put too much reliance upon a particular soil or manure, or especial preparation before sowing or planting—all very necessary things; but the after preservation of the plants from the ravages of insects and other destroyers is equally important, and to effect this no half measures will suffice. In dealing with the various pests that affect the leaves of plants, a yearly recurrence of their appearance in greater or less numbers, according to the season, may be always looked for, and preparation should be made to give them a fitting reception; but with slugs it is different, for if these be once reduced to a minimum, there is comparatively little difficulty in keeping them under. Lime, above all other things, they cannot endure, and where at all troublesome the ground that has been occupied by any crop they feed upon should receive a good supply of it immediately on its removal. At the present time a dressing of this kind should be applied where late Broccoli, Winter Spinach, and Lettuce have stood; and as the refuse leaves and stalks are removed to the rubbish heap, lime ought to be strewn liberally over and amongst them, so as to kill any of the slugs that may be hidden. However numerous they may be, if this course be pursued, together with trapping them under Cabbage and Lettuce leaves, and a regular system of daily examination, few will remain by the end of the season.

Onions.—Choose showery weather for thinning Onions, but, should this not occur, give them a good watering some hours before so as to moisten the soil, or they will not draw freely. In thinning it is necessary to have regard to the different varieties grown; large-growing kinds of the White Spanish type require more room than smaller late-keeping sorts; they may be left respectively 6 in. and 4 in. apart in the rows. Where some are required for pickling it is well to leave sufficient breadth without thinning. In old gardens, especially where the soil is somewhat of a light nature, the maggot in some cases seriously injures the crop to such an extent that the whole is nearly destroyed. Through the maggot being found in the bulb an erroneous impression frequently exists that it enters from the soil, but such is not the case, as it is simply the larva of the Onion fly that lays its eggs between the leaf-blades, where they come to life and descend to the bulb. Soot is highly distasteful to insect life, and in this case, if the beds be dusted over moderately two or three times at intervals of ten or twelve days about the time the fly is depositing its eggs, the crop will often be saved. It is not either desirable or necessary to apply very much soot at each of these dressings, or it will do harm on account of its powerful stimulating properties.

Carrots and Parsnips.—Thin these out before the plants have become drawn, or they will be injured; the former need not at once be thinned to the full extent required, for if left somewhat closer than they ultimately should stand, every other may be drawn for use as soon as they attain the proper size. Parsnips should at once receive all the thinning they will need. Spinach ought to be thinned as soon as the plants are large enough to handle. This vegetable is often neglected by not receiving sufficient room, in which case the produce does not approach in quality to that which it attains when each plant is allowed to stand 6 in. or 8 in. apart in the rows; so treated, the leaves will be three times the size and substance of a crowded crop.

Conservatory.

The rapid growth that roof climbers are now making will necessitate a free use of the knife to keep them properly thinned that they may not become entangled, or sufficiently thick to unduly obstruct the light from the flowering plants beneath them. The choicest and best of these, among which are the hybrid Rhododendrons and Azaleas, will now be going out of bloom, and should at once be removed and placed where they can be continually well syringed and suitably treated to assist them in completing their growth. A genial heat, such as may be secured by closing the house early in the afternoon, immediately after the syringing has taken place, must be afforded them for the next month or six weeks, or until such time as the plants have made sufficient young wood and set their flower-buds. It often occurs, at this busy season, that Azaleas and other hard-wooded plants are left with their seed-pods on them till a more convenient opportunity occurs for picking them off, but it should be always remembered that seed-bearing has a most exhausting effect on all plants, and ought never to be allowed where it can possibly be avoided.

Cytisus and Coronillas. Two of the most useful and effective early spring-flowering plants, should be pruned into shape, and have their branches thinned out where they have become thick and crowded; light and air will thus be admitted, which will enable the plants to break back and refresh instead of having bare hollow middles, as is very generally the case if only the old-flowering growth be trimmed off. These, like most other plants, look best and are most useful when grown in the pyramidal form, and with a judicious use of the knife at this season they may easily be kept to that shape without the aid of sticks or training. To enable them to start freely, and make plenty of young wood, they should be placed where they can be treated much after the same manner requisite for Azaleas. Both Cytisus and Coronillas, after attaining age, and being cramped for root-room, often become infested with white scale, which is one of the most troublesome insects plant growers have to contend against. These fasten themselves on the bark of the stems and on the under sides of the leaves, from which their removal is a matter of some difficulty, and can only be accomplished by using extra strong doses of insecticide. After the pruning has taken place a favourable opportunity will be afforded for using either one or other of the many mixtures now sold for the purpose, as the plants will then be bare of young wood and leaves, which will allow of the insecticide being used of greater strength than would be safe at any other time. Whatever mixture is used it should be applied at a temperature ranging between 80° and 90°, when it will be found far more efficacious than if used in a cold state. Where there are many plants requiring attention in this way, the most economical and surest way of wetting every part of them is by dipping, so as to entirely immerse their heads; and if this cannot be done on account of their size, they should be thoroughly syringed after laying them on their sides, to prevent the liquid from soaking into the soil and injuring their roots. It will be necessary to turn the plants about and assail them from different positions to make sure of every insect, for partial applications are of little use, on account of the rapid way in which these pests spread. It will generally be seen, after a few days, whether the dressing has been effectual or otherwise; and if the insects show signs of life by adhering tightly to the plants, a second syringing should be given. Young plants of both the above can be grown to a useful size so quickly that it is scarcely worth keeping any after they attain age and get stunted, or are liable to insects difficult of removal, like scale. In order to induce Cytisus to flower well they must be grown freely in the early summer months, during which time they should receive a fair amount of pot-room. They should therefore be shifted on as soon as the young growth commences, using for the purpose good fibry loam, and a very little rotten manure that has been laid under cover for a time so as to be dry and sweet.

Camellias.—Continue to afford these every encouragement by closing the house early, maintaining, at the same time, plenty of atmospheric moisture by syringing the plants freely overhead and well wetting the pathways, floors, &c. Camellias will bear much more heat at this time of year than they generally receive, and if blooms be required early they must be brought forward now, as the least artificial heat applied late in the autumn will cause them to cast their buds, or only to produce comparatively worthless flowers. Any that are limited as to pot-room must be kept well supplied with water if the plants be in a healthy state at the roots, and of this the top is a sure index. If with plenty of leafage of a dark green colour they will absorb a quantity of water for some time to come, and can scarcely have too much, provided the drainage be thoroughly efficient. Others that are making but an indifferent growth and show want of vigour and general activity clearly indicate that something is wrong at the roots, and they must be watered with great care, or the evil will be aggravated by causing others to perish. There is so much difference of opinion among growers as to the proper time of re-potting Camellias that it would appear of little importance whether carried out now they have made their growth or before they commenced to do so. Those who prefer to wait, or who had not the opportunity at an earlier date, should not defer the operation longer than it can possibly be avoided, for when the buds get large, any check in this way would be likely to throw them off.

Liliums.—Where these were potted as recommended—to leave a depth of several inches from the rim of the pot to admit of a surface dressing—it should now be applied; but before so doing, it will be advisable to get in what stakes are necessary to tie out the plants, as the positions of the bulbs can be more easily ascertained before the extra soil is added; and any injury that might result from the sticks coming in contact with them would thereby be avoided. Good, rough lumps of fibry loam or peat, or both combined, should be used for the top-dressing, in which the stems will root just at the crown of the bulb, and feed upon with great avidity. If the pots of these

can be placed in some open position, secure from strong winds, they will make far better progress than if kept under glass, unless they should be required for early blooming, in which case a light airy place must be appropriated to them, or the under leaves will turn yellow and fall off. Should any be removed from the protection of glass to the open ground, they should receive a slight shade for a day or two, till they become inured to the change, or the sun will disfigure the leaves. The pots, too, ought to be sheltered by having some loose, littery material laid round them to prevent a too rapid desiccation of the roots, which, to such moisture-loving plants as free-growing Lilies, would prove highly injurious. Manure-water may now be applied to them occasionally with great advantage, and more frequently as they advance in growth and fill their pots with roots. Any that are standing in pits should have the sashes removed by day, and be kept well apart to admit a full play of light between them, that the stems may be sturdy and strong and the leaves healthy.

Cyclamens.—The starring of these that used to be practised by drying them off during the summer months has of late years been discontinued, and a more liberal and rational treatment is now pursued, the result of which is most satisfactory, as may be evidenced by the splendid specimens that many growers exhibit at the metropolitan shows. These are grown freely and continuously on without rest or check of any kind from the time they make their appearance above the soil in the seedling state till they attain sufficient size to carry at least 100 blooms, and this in a little more than a year from the time of sowing the seed. If grown on again after they have done flowering, the bulbs increase in strength for several years and make a fine display, although the individual blooms may not be so large as those on younger plants. For the last two or three seasons we have planted the whole of our stock out in prepared beds in partially shaded borders; and it is a practice I can strongly recommend, not only for the saving of time and labour in attending to them, but also for the increased state of health and vigour of the plants when taken up in the autumn compared with others treated in pots during the summer months. The bed or border for planting them in should be so situated as only to get a few hours' sun either in the forenoon or evening, and in such a position that they can be easily attended to for watering or syringing, the latter of which they require almost daily to preserve the leaves fresh and free from red spider. In preparing the bed, the natural soil should be dug out to a depth of 6 in. or 8 in., and be replaced with rough fibry peat pressed firmly in, or failing that, leaf-soil and loam may be substituted in the proportion of three parts of the former to one of the latter. The plants should then be turned out of their pots without disturbing the roots, and planted sufficiently far apart for the leaves of each to stand clear, after which give a good watering and frequently syringe or damp overhead whenever the weather is dry and warm. Those who prefer keeping them in pots should now place the plants in pits or frames in a genial atmosphere, to promote which the syringe should be applied, shutting up in the evening afterwards.

Cinerarias.—Any choice kinds of these now going out of bloom, and which it may be desired to perpetuate, should have the flower-stems cut away and be then planted out in a north or shady border to form suckers. To enable them to secure these, they must receive plenty of water, and be kept clear of green fly, or the plants will die outright, as they possess little vitality after the exhaustive effects of flowering. Seedlings of these are much more vigorous, and make better plants for decorative purposes than any that can be grown by the above method, and, except for special purposes, such as for exhibitions, &c., the latter are preferable. A sowing should now be made to flower late next season, and those now intended for Christmas should be carefully attended to, in order to push them forward and get them sufficiently strong. No place suits Cinerarias during the summer months better than a common garden frame in some light shady position, and the natural soil, with just sufficient ashes over it to keep out worms. When they have to be shaded by the aid of mats or other appliances—it is very rare they are on at the right time—and the effect of strong sunlight is anything but favourable to the growth or well-being of either these or Primulas at this season of the year, so that the remarks made with reference to the former apply with equal force to the latter. A moist atmosphere must be maintained by damping the floor of the pit or frames on which the plants stand, and syringing them overhead just before closing.—J. SHEPARD, Woolverstone Park.

Orchids.

Every possible means should be resorted to in order to keep the temperature of the cool Odontoglossum-house down, for if it be allowed to get too high the plants will not thrive. The fire-heat in connection with this house should be turned off altogether, as henceforth it will do more harm than good. The house should be carefully shaded on sunny days, and air freely admitted at all times,

leaving some on all night; it is best to have the bottom ventilators covered with coarse gauze or perforated zinc, so as to keep the insects from getting in and damaging the plants. The cool *Odontoglossums*, *Masdevallias*, and similar plants should be liberally supplied with water, going over them at six o'clock in the morning, or as soon after that hour as possible, and watering those which require it with a spotted pot; any water accidentally dropped into the young growths will then be dried up before the heat of the day has set in; water should be thrown about the house several times a day, in order to keep up a moist atmosphere, but the plants should not be syringed; if the air, shade, and temperature of the house be attended to, the syringing will not be necessary, and if it be not carefully used it often does mischief when brought into use; in the case of any class of Orchids it should only be employed early in the morning and never during the heat of the day. The cool *Odontoglossum*-house should be a lean-to with a north aspect, but if it face a few points east or west, it is of no importance. Ventilation should be so arranged that the air may circulate freely around and under the plants. Underneath the stage or some other convenient part of the house should be cemented so as to hold an inch or two of water; if the stage on which the plants are placed be a slate one, it should be cemented round the edges and along the joints so as to make it hold water, and light wooden lattice-work from 2 in. to a foot in height should be placed over it for the plants to stand on; or, instead of this, they may be set on inverted flower-pots. Corrugated iron trays may be placed on an ordinary wooden stage and kept full of water without fear of rotting it; it is absolutely necessary that a surface of water of some extent should be present in the cool *Odontoglossum*-house during the summer time. Attend to giving air, shade, and moisture in the other houses, and regulate the temperature as recommended last week.—JAMES O'BRIEN.

Hardy Fruits.

At this season, when all kinds of hardy fruits are growing in the most luxuriant manner, it is well to bear in mind that next year's crop depends, in no small degree, on the treatment that the trees receive this year; therefore they must be kept clean and healthy to bring about successful results. One of the most important operations connected with fruit culture now demands attention, viz., the pinching, stopping, and regulating of shoots. Summer pinching of the new growth, to induce fruitfulness, is much preferable to winter pruning, for nearly all kinds of fruit; and, if done properly and at the right time, the best results may be anticipated. Frequently, for the sake of appearance, the shoots are pinched in too closely, and growth thereby is too much repressed; sometimes they are allowed to run wild, and then removed wholesale—a proceeding which is ruinous to the commonest fruit; extremes either way should be avoided. Apples, Pears, Plums, some kinds of Apricots, and all kinds of Cherries, except Morellos, bear their fruit on side-shoots or projecting spurs, and therefore the new growths of these, as a rule, should be stopped at the fourth or fifth leaf; if pinched in closer than this, the buds "close home" break into new growth in lieu of forming fruit-buds, which is the object desired. Let it be granted, that by leaving them there the spurs in time become long and far removed from the wall, then, to a certain extent, the wall becomes useless as a protector; but it is an easy matter to remove annually at the winter dressing a few of the longest spurs, and so by degrees renew those on the entire tree. Of course, when stopping has been once done at the distance named, any supplementary growths of this season may be stopped at the first joint, and repeated as often as growth makes the operation necessary. If, as sometimes happens, new growths have been left too long without having been removed or stopped, do not remove them all at once, as that would give the trees a severe check; but take off a few shoots at intervals of three days till all are removed. It is always advisable, however, to obviate this by stopping as growth progresses. Peaches and Nectarines that were not sufficiently disbudded should have their new growth pinched in rather closely, this, in their case, being preferable to disbudding at this late period. If not already done, the fruit should be thinned at once, and the same remark applies to other kinds of fruit that have set thickly, particularly to Pears. Water Strawberries in the absence of rain, as they soon suffer if they lack moisture at their present stage.—W. WILDSMITH, *Heckfield*.

PLATE XXIV.

HARDY MAGNOLIAS.

(WITH A COLOURED FIGURE OF MAGNOLIA LENNEL.)

The *Magnolias*, of which a full account was given in Vol. VIII. (see p. 269), constitute a genus of highly ornamental small trees, with large entire leaves and terminal solitary Tulip-shaped white or purple flowers, which are either agreeably fragrant, or, on the contrary, have a disagreeable odour. All the kinds, which are perfectly hardy, come from North America, and, with the exception of the beautiful evergreen, *M. grandiflora*, which is not quite hardy, they are all deciduous. *M. grandiflora*, which is more or less tender in our climate, and of which there are several varieties, requires the protection of a conservative wall. It has large white flowers, which are very fragrant, and are produced throughout the summer and autumn. *M. macrophylla* is unquestionably the finest of all the species, on account of the large size both of its leaves and flowers; the latter, which open during June and July, measure from 8 to 10 in. in diameter; they are of a white colour stained at the base of the petals with purple, and sweet-scented. This kind often thrives badly in England, but where that is the case it will generally be found that it is planted in dry situations, and that, consequently, it suffers from drought in summer. *M. auriculata* has large leaves, mostly in tufts, at the ends of the branches, and rather large greenish-white flowers, which have a disagreeable odour. Its blossoms open in April and May. *M. pyramidata* has shorter leaves than *M. auriculata*, of which it is evidently only a variety, and quite pyramidal in outline. *M. cordata* has broadly ovate leaves, tomentose on the under sides and quite smooth above; its flowers, which are yellow, are produced in June and July. *M. acuminata* (the Cucumber tree of the Americans) has oval, acuminate leaves 6 in. or 7 in. long, and 3 in. or 4 in. broad, pubescent on the under surface. Its flowers, which are produced from May to July, are yellowish-white and slightly fragrant. It is a very robust and free-growing kind. *M. tripetala* (the Umbrella Magnolia) has leaves from 18 in. to 20 in. long, and 7 in. or 8 in. broad, lanceolate, the adult ones being smooth, and the young ones pubescent underneath. Its flowers, which are large (7 in. or 8 in. in diameter), have large, flaccid petals of a greenish-white colour, and are produced from May to July at the extremities of the last year's growth. They have a sweet but heavy scent. *M. glauca* (the Beaver tree) has elliptic, obtuse leaves, the under surfaces of which are glaucous. Its flowers, which are produced from June to September, are white, 2 in. or 3 in. broad, and very fragrant. There are three or four varieties of this, one with nearly evergreen leaves, and another with long narrow leaves. *M. Thomsoniana* is another tolerably distinct variety with rather large leaves. *M. conspicua*, sometimes called *M. Yulan*, is a showy kind, distinguished by its flowers appearing before the foliage. It has obovate, abruptly-acuminate leaves, which, when young, are pubescent, and expand after the flowers have faded. It is a remarkably showy plant when covered in spring with its white, Tulip-shaped, sweet-scented flowers; there are numerous hybrid varieties of it now in cultivation, all more or less tinted with purple, similar to the hybrid *M. Soulangiana*. *M. conspicua* is quite hardy, but it produces its flowers so very early that when in blossom it requires protection. *M. purpurea*, sometimes called *discolor*, has obovate, acute, reticulately-veined leaves, of a deep, glossy green colour. Its flowers, which are produced from March to May, are purple outside and white within. This kind is quite hardy, and forms a bush from 3 ft. to 4 ft. high. *M. gracilis*, or *Kobus*, a less hardy kind than some of the others, differs from *purpurea* in having paler green and narrower leaves, and in the flowers being longer and more slender in form, the points of the petals, which are dark purple on the outside, are slightly turned inwards. *M. Lennelii*, originated some years ago in Italy, is said to be a natural hybrid between *Yulan* and *gracilis*, and has, as will be seen by our plate, the more highly-coloured flowers of *obovata*, but it is difficult to distinguish among the many varieties now cultivated in different gardens. *M. Campbellii* is a new introduction from the Himalayan Mountains, with magnificent foliage and red flowers. Its hardiness has not yet been sufficiently tested, but it is expected that it will live out-of-doors, at least, in the south of England. G. GORDON.

Dr. SCHWEINFURTH's recent journey through the desert from the Nile to the Red Sea has resulted in the addition of many unexpected plants to the Egyptian desert flora. Dr. Ascherson has also been able to extend Professor Jordan's sketch survey of the Little Oasis, made in 1874, very materially; and owing to the friendly reception given him by the inhabitants, has gathered many details of interest respecting their domestic life. He reports a custom here which is of quite unknown in other parts of the Nile valley, namely, that of fire-making by rubbing together two dry pieces of the midrib of the Date Palm leaf.

LIQUID MANURE IN GARDENS.

ONE of the common mistakes made by amateur cultivators of flowers is that of over-manuring. To grow plants properly, little or no crude manure should be incorporated in the soil, as it induces a too luxuriant growth of foliage and wood at the expense of the flowers. The liquid form is the best in which to apply manure, and this should be made very weak, especially if it be of a stimulating character, such as guano. The chief value of liquid manure is that its effects are perfectly controllable, and can be made constant, either to produce an exuberant growth and sustain it, or to produce any lesser effect, as may be desired. If wood and foliage be desired, the manure should be given as soon as the buds begin to swell in the spring, or when the leaves commence to develop. This growth can be kept up during the season by frequent applications of the liquid, but should never be continued beyond the first of August, as then the growth naturally begins to cease, the wood begins to harden as the season advances, and ripens for the winter rest of the plant. If the liquid be applied after the commencement of this preparation for rest, the growth is unnaturally continued, and the wood, not having time to ripen, is winter-killed. When the production of fine flowers is desired, liquid manure should be applied when the flower-buds begin to show themselves prominently and commence to swell; if then causes a larger development of the petals and an enhancement of the colors; but if applied too early, it is liable to produce monstrous flowers. Thus applied to Strawberries, for instance, it causes larger and more evenly-developed fruit to be produced. Applied to Roses, the flowers are largely increased in size and also in brilliancy of colour. For Zonal Geraniums and similar plants bedded out, the supply must be moderate and continuous; while to plants bedded out for their peculiar foliage it should be given more frequently, so as to cause the production of larger and higher-coloured foliage. With some plants, however, such as bulbs (*Hyaacinths*, *Tulips*, &c.), the strength of the flowers is dependent upon the luxuriance of the leaf growth of the previous season, the results of their vital action being stored up in the bulb for next year's blooming. In such cases the plants should have a supply of the liquid for some time after they have done blooming. When applied to fruit trees, the best time for its application is after the fruit has set and it begins to swell. To give it when the flower-buds show themselves is useless, as the size and colour of the flower have little if any influence upon the size and flavour of the fruit. If the manure applied be too strong, a too luxuriant leaf growth is brought about, and there is danger of the tree casting its fruit prematurely, the whole energies of the plant under the stimulating action of the manure being expended in the production of leaves. As the season for the maturing of the fruit approaches, the supply of manure should be gradually withheld, as otherwise the fruit, although large and fair, would become watery and lose much of its proper flavour. The best mode of applying liquid manure to plants or trees in the open ground is to make holes near them, or toward the extremities of the circle to which their roots extend, with a crow-bar or stout stake, from 1 to 3 in. in diameter, driven in to a depth of from 12 to 18 in., and then withdraw, filling the holes with liquid. It thus soaks away into the soil immediately in contact with the roots, and nothing is lost by evaporation, as is the case when it is applied to the surface of the soil. This is also an admirable mode of watering plants in the open ground during a drought. The number of these holes should vary with the size of the tree or plant, one hole to every 2 ft. square of ground being generally sufficient. If the weather be very dry, the manure should be much diluted; and if the weather be wet, it may be applied of greater strength. As a rule for the preparation of liquid manures for out-door purposes as above recommended, the following quantities of various manures to a hogshead of water (sixty gallons) will give the average strength at which it should be used, if applied every two weeks during the season:—One bushel of horse manure, or the same quantity of sheep manure, or half a bushel of hen manure, or half a bushel of soot, or six pounds of guano, allowing the liquid to stand two or three days before using, stirring it once a day, and using the clear liquor. R.

Cold in its Relation to Height.—According to some remarks of M. Martins, of Montpellier, cited in the "Belgique Horticole," the intensity of cold at night diminishes up to a certain height. This phenomenon was tested by M. Martins by placing thermometers in the Botanic Garden, and at various heights on the cathedral tower. In clear nights the increased warmth at a higher elevation is the most perceptible; in dull nights there is little or no difference. The reason of the greater injury inflicted on the lower branches of shrubs, &c., is thus accounted for.

Lighting of Exhibition Tents.—In "Le Nord-Est," published at Troyes by M. C. Baillet, M. Raoul recommends horticulturists to partially coat over the tents in which they exhibit their flowers with boiled Linseed oil. Thus treated the material of which the tent consists becomes more permeable to light, and the plants are shown off to greater advantage. We fancy, however, that the effect of plants under canvas is all the finer by reason of the subdued light.

THE FRUIT GARDEN.

LARGE VINES BEST.

I HAVE given this subject much consideration, and have come to the conclusion, from my own experience, and from that of others who have had to do with Vines on the extension system, that for the main crop of Grapes, where little or no forcing is required, large Vines are certainly better than the old single rod and spur system. Vines would do better, and last longer in a fruitful state, if allowed to fully develop themselves. Many have seen or heard of the Hampton Court Vine, and of the enormous crops which it has borne for a great number of years. It is about eleven years since I saw it, and it was then carrying a heavy crop of bunches about half swelled, and to all appearance, judging from the foliage, it would finish them well. There are several places in the country where there are large Vines as well as the one just mentioned. These have for the most part been little heard of beyond the neighbourhood where they are growing. Some of the finest Vines I have ever seen in different parts of the country were those that were planted outside and brought through the front wall into the house, and allowed to grow and fill it.

The large Vine at Hensol Castle, in Glamorganshire, was a cutting from the Hampton Court Vine, and was planted by the late Mr. Crawshaw some seventy years ago in a prepared border outside, and introduced into the house through a hole in the front wall at the centre of the house. The stem of this grand old Vine, before entering the house, is nearly a foot in diameter. As soon as it enters it branches off horizontally right and left in two leading shoots, which have grown to each end of the house. These shoots are trained close to the wall-plate of the front lights, and are supported by blocks of wood, about 6 in. long, placed below them to keep them off the sill of the front wall. From the two leading shoots twenty-one rods are trained up the rafters at regular distances to the top, and they fill the house completely. The border is 72 ft. in length and 45 ft. in breadth, with a good fall to the south. The Vinery is 72½ ft. by 17 ft. wide, and the whole ground surface inside is covered with flagstones, which slope from the 3 ft. walk at the back of the house to the front wall, say 2½ ft. of a fall. Of the general treatment of this Vine I can say but little; but Mr. Francis is entitled to great credit for the promising state it was in when I saw it the other day. Mr. Francis, I may add, a staunch supporter of the extension system. This Vine produces heavy crops of well-finished Grapes, which are generally ripe some time in August, but their maturity depends a great deal on the season, as no fire-heat is used at any time during its growth. The berries, as a rule, are large and well coloured. Of the bunches, which average from 1½ lb. to 3 lb. each, Mr. Francis cut last year 900 from it. The Grapes are not subject to shanking unless when the crop is too heavy. It is a fact well known to most cultivators that heavy cropping is one of the principal causes of shanking. This Vine, too, is seldom attacked with red spider. As the house is not heated the Grapes do not keep long; on the contrary, if they are not all cut before the middle of November they begin to damp off very much, and in a short time become useless, but with a little fire-heat to expel damp they would keep much longer. I was pleased to see that Mr. Francis was bringing up some young rods from the bottom of the main shoots to take the place of some of the older ones. I would strongly advocate the system of never allowing the rods to get very old, as it becomes difficult to get the old wood to break if left to go too long.

There is another good Black Hamburg growing at St. Fagons Castle, near Cardiff, though not by any means so old as the Hensol Castle Vine. It fills a house 30 ft. long by some 14 or 15 ft. wide, and is at present in excellent health. When I saw it the other day the young shoots were from 8 in. to 9 in. long, showing strong bunches, which I have no doubt will turn out well. Mr. Crossing informs me that in 1873 he found the Vine in a weak state, with a couple of canes of from eight to ten years' growth. In the following spring it broke weakly, and did not show as much as a bunch of fruit. All the shoots from the main stem were trained to their full length and ripened well. Two of these were trained horizontally, right and left along the front of the house in a line with the bottom of the rafters; when pruned in the autumn, they were left 13 ft. long each from the main stem, reaching within 2 ft. of either end of the house. All the others were removed, but he still retained the old canes, which again broke weakly in 1875, while the young canes broke well. From the young canes just mentioned twelve rods were allowed to grow, at equal distances apart, to the top of the house, and they have entirely filled it, and each was allowed to carry a bunch of Grapes, which weighed from 3 lb. to 4 lb. The whole portion of the Vine was cut out, and the young rods look all that could be desired. Mr. Crossing says he is never troubled with red

spider in this house; the floor is all covered with flagstones, and a few large Orange and Myrtle trees are wintered under the Vine, besides a few other plants. He can say little about the border or its formation. By mulching it with manure from the farmyard, he has induced the roots to come within 6 in. of the surface.

The two Black Hamburgs at Dumfries House, in Ayrshire, are reputed to be from 140 to 160 years old, and finer Vines and better bearers could not be desired than they are, even at this day. The Vinery is an old-fashioned structure 60 ft. in length and some 9 ft. or 10 ft. wide, the roof is at an angle of 45°, and it is heated by means of an old-fashioned flue. The two Vines fill the house, and would have filled a house long ago twice its size. The treatment which the Vines received during the six years they were under my charge was very simple. They started into growth of their own accord about the middle of February. The house was kept close, and the Vines syringed twice a day till the buds burst into leaf. After that they were given air as required, but were never syringed afterwards. The passage and surface of the floor were damped down several times daily, and were never allowed to get dry at any time. As the season advanced, and the house got filled with leaves, it was damped down, after being shut up in the afternoon, with a little liquid from the cow-house diluted in water. Care was taken, however, not to have it too strong, in case the ammonia which it contained might injure the foliage. These old Vines, spreading out in luxuriant health, extending from one end of the house to the other, carried splendid crops of fine Grapes. The bunches would run from 1½ lb. to 3½ lb. The berries were large, well "hammered," and as black as Sloes. The leaves were strong, healthy, and green, till the last bunch of fruit was cut. They ripened off a beautiful golden-yellow, and were allowed to fall as they ripened of their own accord. As soon as their leaves were off the Vines were pruned. I tried to have the young and old wood as equally divided over the house as possible; and by allowing a few leading shoots to start from the bottom every year, and cut back to a proper distance, I had rods on the Vines at all stages from one to five years old. By adopting this plan, the rods from the main stems were not allowed to be more than five years old. The rod reached the top of the house in four years, and fruited the fifth, and was then cut down close to the main stem, where another cane had been started to take its place. I never saw a red spider in the house. The late Mr. David Murdoch, who knew the Vines for fifty years, and who for twenty years of that time had charge of them himself, told me that he never saw a red spider in the house, and that they had always borne heavy crops of fruit ever since he knew them. The glass is old, in small squares, and very open at the over-lap, which admits a great deal of air over the whole surface of the roof. This, I have often thought, added texture and strength to the foliage. The Vines are planted outside and brought through the front wall. There has been nothing done to the border for years, farther than covering it up with stable litter in the autumn, and emptying the tank from the cow-house on it all through the winter. The border and adjacent ground has a good fall to the south. The River Lugar runs close by the gardens at a distance of about 100 yards from the Vinery, but I don't think the Vine roots go near it. I may add that I am filling two Vineries here with one Vine each, on the same principle as that just described at Dumfries House. The variety is the Black Hamburg.—A. PETTIGREW, in "The Gardener."

THE FOUR SEASONS STRAWBERRY FROM SEED.

In a letter from M. Fallot, Chief Gardener at the Chateau de Maintenon, published in the "Bulletin de la Société d'Horticulture d'Eure et Loire," the writer strongly urges on Strawberry growers the advisability of cultivating this variety from seed rather than from runners or cuttings, wherever it may be practicable. There is a wide difference between beds of plants grown on the two systems. The robust habit of the seedlings, their greater productiveness, and the superior beauty and size of the fruit, give them almost the appearance of being different varieties of the same plant. M. Fallot has largely experimented on the three usual methods of propagation by division, by runners, and by seeds, with the result that estimates their merits as being in the inverse direction of the order in which they are named, that is to say, the roots are inferior to runners, and both inferior to seedlings. The comparative ease, however, with which a large plantation may be made from cuttings or runners has great temptations for the cultivator, whose time is taken up with a thousand other cares. Last year being a damp one, M. Fallot's crop was most successful, the fruits being so large and fine that when brought to table they were thought to be a new variety. The following is his method of culture.—About the middle of June the best fruit on the finest plants are chosen for seed. They are dried in the sun, and the seeds are washed out, rejecting those which remain floating on the surface.

They are sown in the beginning of July in a light soil, raked over and covered with straw; they are shaded until germination has taken place, when more light is admitted gradually day by day. The sowing may be made in pans, which may be exposed to the sun or placed in the shade, as may be thought desirable; they should be watered daily. During the last week in August they are pricked out, leaving about 4 in. between each plant, and in March following they are planted out 12 in. or 15 in. apart, advantage being taken of the first fine days for the operation. All runners are diligently nipped off during the whole year, and also flower-buds until the middle of June. From the end of July the plants are in full bearing until the first frosts set in. The third year they are cleared of all their dead leaves, in March all runners being vigorously destroyed. Towards the middle of May straw is placed between the rows. The second crop is found to be much more abundant than the first, and to last from the 20th of May until the frosts set in, the plants growing much more rapidly and vigorously than if they had been raised from cuttings or runners. From about the middle of June the plants are well watered every day at the rate of a gallon of water to every ten plants. After the second crop the plants are pulled up and destroyed, the order of operations being—first year, sowing; second year, first crop from the end of July only; third year, a full and abundant crop from May 20 until the first frosts set in. The seedling Four Seasons Strawberry being more vigorous in its growth than the others, continues bearing to a later period, but it is not adapted for forcing, the plants produced from division or runners being preferable for this purpose. It is hardly necessary to remind growers that this variety is the only one that can be reproduced from seed; the English and American sorts not only do not yield the variety to which they belong, but produce a mixture of as many kinds as there are plants. They must, therefore, necessarily be propagated by means of runners.

The Grape Market.—Fruiterers' profits on really fine Grapes are something enormous. According to "The Gardener" Grapes are often bought at Christmas time for 7s. 6d. per lb., and retailed at 21s.—a respectable profit, certainly, but such as debarred all but the most wealthy class from purchasing. No doubt, the price to the producer was remunerative enough, but we fear this is an instance among many of the fact, that notwithstanding the great extension of Grape-culture and the comparatively low price at which the grower can, with the aid of cheap glass and improved appliances of every kind, afford to sell Grapes, the consumer does not yet share the benefit therefrom to the extent that should be expected—a benefit which, could it be realised, would add an impetus to Grape-culture in this country to which it would be difficult to conceive a limit. Of course, it may be said that a pound of Grapes is just worth what it will bring in the market; but the British public will never reap the full benefit of the fact that first-rate Grapes can be produced for at least nine months of the year, with a respectable profit to the grower, at 4s. per lb., till the retailers are content with 50 per cent. profit; and then the demand for Grapes would run increase fourfold; in the long run, the extent of the trade of the retailer would make up for more moderate profits: the public would get Grapes cheaper, and the field and call for British-grown Grapes would make Grape-culture more available than it is as a means of livelihood.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Vine v. Smoke.—In a paper addressed to the French Academy of Sciences, M. C. Hussen calls attention to the disastrous effects of smoke on vegetation. For many years proprietors of vineyards situated in the vicinity of inconvenient neighbours, and various chemists have confirmed their statements.

Russian Apples and Cold.—Russian varieties have gone through from 38° to 44° of cold, Duchesse of Oldenburg lives at 44°, dead at 46°; Alexander, 40°, dead at 44°; Red Astrachan, 33°, dead at 44° below zero. Tetofski is the only variety of the Apple that lives at 53° below zero, while some of the Siberians have been killed with 59° below zero.

Saving a Crop of Grapes.—Mr. A. Crambe tells us in "The Gardener" how he saved a crop of Grapes endangered through the bursting of a boiler in January when they were coming into flower. "I had about thirty common water-pots introduced twice a day, filled with boiling water, which enabled me during daylight to keep up a heat of from 60° to 55°, and occasionally, when favoured with a little sunshine, the thermometer rose to 70°, which caused me to ventilate slightly. By the means described, I have been able to save my crop; and more, the weight and quality are equal to those of any preceding year."

Hardy Peaches.—In the report of the Orchard committee of the Michigan Pomological Society for 1875 mention is made of hardy varieties of Peaches as examined in the orchard of Mr. C. T. Bryant. Hill's Chili is reported to be the hardiest in wood and bud. Keyport White and Red Raripere come next; and these are followed in order by Early Barnard, Jacques Raripere, and Early Crawford. Hale's Early compares with the Early Crawford as to bud, but in wood has proved tender.

THE KITCHEN GARDEN.

MUSHROOM CULTURE IN CELLARS.

MUSHROOMS may be, and often are, grown to perfection in many less ambitious structures than the Mushroom-house properly so called. Any kind of outhouse, in fact, will answer for the growth of autumn and early winter Mushrooms. One of the best crops which I have ever seen was grown in a cellar at West Hill House, Highgate. Of the appearance of the beds in this instance some idea may be formed when I state that from one 12 ft. long and 8 ft. wide were gathered as many as 160 lbs. of Mushrooms between October and February. Other beds were also equally productive, though all of them were without the means of being warmed artificially. They merely occupied a dry dark cellar under the dwelling-house, where no hot-water pipes or other mode of heating was employed. Yet, with the thermometer down as low as 40° they remained unharmed. The usual temperature, however, ranged from 48° to 55°. The beds were formed of short manure from the stables, 16 in. or so in depth. Previous to using the manure it was thrown into a heap to heat and get rid of its superfluous steam and moisture; it was then spread out for a day or two to dry and cool; after that it was thrown together again for a few days more, and then it was made up into a bed. In forming the latter, however, care was taken to have it made very firm by means of treading or beating, and as soon as the heat had risen to the proper point it was spawned with Milltrack spawn, of which half-a-bushel is sufficient for a bed 10 ft. square. This, broken into pieces about the size of small Apples, will, placed just in the manure, and firmly

Mushrooms from Milltrack spawn.

covered 2 in. deep with any good garden soil, produce Mushrooms of first-rate quality in six weeks in a temperature of 50°. Beds thus treated never fail to bear satisfactorily, not only in regard to quantity but size, many of the specimens weighing 4 ozs. each, and excellent in flavour. It will thus be seen that this plan of growing Mushrooms in cellars is worthy of imitation; especially in places—and there are many—where there is no proper Mushroom-house, and even where there is, empty cellars might thus be turned to profitable account. J. M.

OBSERVATIONS ON THE PLAN AND MANAGEMENT OF THE KITCHEN GARDEN.

It would be a difficult task to say why the culture of the kitchen garden should be the last of which cultivators as a rule get a thorough knowledge, seeing that it is the most generally useful of all, for a kitchen garden is indispensable wherever a gardener is kept, whereas other branches embracing luxuries such as forcing and flower gardening in their many and various forms, are indulged in according to the taste and means of the owner, and vary in their requirements in almost every establishment. I believe that the exaggerated notions of the great skill required to grow exotic fruits and flowers under glass has had a most depressing influence on the cultivation of kitchen garden crops and hardy plants generally, while the favour that exotics received at horticultural exhibitions was, up to the last few years, more likely to discourage still further the cultivation of kitchen crops, and was the means of impressing young gardeners with the idea that vegetable and hardy fruit culture was only fit for cottagers or amateur cultivators. In many gardens the ornamental or show portions of the grounds have so overgrown the amount of labour at disposal, that the useful but less conspicuous portions are robbed of the necessary attention. If the kitchen garden crops require screens to hide them, the fault must lie at the door of the cultivator, and not in the crops themselves, for I am not acquainted with anything that yields more lasting pleasure to a gardener than a well-ordered kitchen garden. There are at

all seasons some objects of interest in crops at various stages of growth that it would be difficult to say which is the most interesting season, for he who is to achieve satisfactory results must look far ahead and provide against the influence of adverse seasons, the effects of which will well-nigh baffle the most experienced cultivators, even when well acquainted with the best varieties, seasons for sowing, and the most favourable soils and positions for the site of the kitchen garden.

In pointing out a few simple rules that tend to make the kitchen garden of equal interest with other portions of the garden, I would remark that it is on the small matters connected therewith that success or failure rests.

In laying out kitchen gardens we must set our minds entirely on the object we desire to be attained, viz., that its usefulness will be measured by results; and, whatever our notions on straight lines in pleasure grounds may be, there can be no question of their thorough adaptation for the end in view, therefore boundary and intersecting walls and walks should be perfectly straight and parallel with each other. I may here observe that upon the walks and edgings associated with the walls will depend greatly the aspect of the whole garden. Good walks are indispensable, not only for comfort in walking, but should be capable of bearing the carting and wheeling necessary to every portion. The outer or boundary walk, at least in large gardens, should be wide enough for carting manure and other materials expeditiously to all parts; they must be well drained, and present a firm, moderately rounded surface, and kept at all times scrupulously clean from weeds and litter of every kind. By choosing dry periods for the operation of carting much unnecessary labour is saved, as the surface of the walk should be broken up as little as possible under any circumstances.

As an edging I find nothing to equal Box, when kept in good condition, but it must not only be well laid at first, but carefully attended to afterwards; it should be clipped in May, or early in June, with very sharp shears by experienced workmen, and should form an unbroken line of exactly the same proportions throughout its entire length. It is not in their use, but in their abuse, that Box edgings have lapsed into their present state of disrepute. When wheeling through them, and trampling on them, is practised, gaps and patches are formed which destroy all pretensions to beauty; to obviate this defect portable bridges for wheeling over, and stout stakes driven firmly in to protect the corners, preserve the edgings intact for an indefinite period.

The walls are conspicuous objects, and upon the thoroughly furnished aspect which they present at all seasons, will depend a great feature of the garden. I do not recommend the exclusive planting of special varieties on most favoured aspects, for I believe that better results in the way of succession for a long period, are achieved by adopting some portions of each kind on distinct aspects, but they should be grouped for the more ready manner in which they are protected from frosts, birds, and other enemies. Fruit tree borders at the bases of walls should not be less than 10 ft. or 12 ft. wide to allow of a 3 ft. alley being kept clear for attending to the trees, and as an undisturbed root-run: this should be always mulched during the summer. Borders with south aspects are invaluable for the earliest and latest crops of vegetables, and cool, shady borders for those in the mid-season.

The main quarters should be kept perfectly clear of trees, and deeply cultivated for general crops, or a single row of espaliers or cordons may divide a narrow border from the walks, as they form most useful auxiliaries to the fruit supply. Pyramids and low bush trees form good central or divisional objects, but standards should be grown either in the orchard or in spaces specially devoted to fruit culture, where the main portion of bush and fruits may be also grown, as a mixed system is not by any means so satisfactory to either fruit or vegetables as when they can each receive treatment congenial to their several wants. Strawberries form a good rotation crop on ordinary vegetable quarters, and, if not left in one position more than three years, the land is decidedly benefited by such change.

In planning the rotation of crops it is well to bear in mind that crops of an opposite character generally succeed best, but, by the aid of deep cultivation and liberal manuring,

market growers fill whatever ground is vacant at the time with those crops that are most in request, whereas private growers, with whom quality of crop stands before quantity, can arrange a pretty correct plan of cropping before the winter cultivation. Root crops such as Salsafy, Scorzonera, Parsnips, &c., are decidedly preferable grown in deeply cultivated land, without any addition of fresh manure. A routine, such as the following, answers well:—First year, Onions, the ground afterwards manured and deeply dug, and planted with Cabbage in autumn; second year, Sprouts; third year, ground cleared of stumps and weeds, and prepared for celery trenches, after which Peas, Potatoes, Strawberries, &c., succeed well; but one rule should be followed with all, viz., to drill all seeds and to plant all plants in straight lines of equal distance apart each way, not only for the sake of appearance, but for the expeditious manner in which the operation of cleaning the crop may be performed, compared with broadcast sowing: immediately the lines of seedlings are visible run the Dutch hoe between them, which not only destroys the weeds, but greatly encourages the growth of the crop. The rows should then be weeded, and the crop thinned as early as possible, for all surplus growth is at the expense of the permanent crop. I cannot too strongly condemn mixed cropping, or sowing two crops together, as Lettuce and Parsley amongst Onions, and Broad Beans amongst Potatoes; this is of itself enough to give a weedy self-sown aspect to the best crops, and no advantage is thereby gained. It is quite distinct from intermediate cropping, which, in some cases, is highly favourable to both. Parsley, herbs, and salads, that are in daily demand, should be grown on narrow borders, clear of the walks but convenient for gathering. As regards varieties I would not recommend an experimental system of growing all new kinds, as the most likely to furnish a constant and reliable succession, nor yet be prevented by prejudice from adopting any real improvements. I would rather recommend a few of the most promising kinds to be tried each year, and select from them for permanent varieties, when convinced of their superiority by comparison of growth, and suitability to locality, &c.

Seeds should be procured from reliable sources as nothing is dearer in the end, or more vexatious, than bad seeds. If you cannot rely on all the seeds germinating it is impossible to have satisfactory results, and patches and gaps are a great eyesore. I would also say—select for yourself, for all collections of seeds contain some that you do want and many that you do not. No one can select for you without knowing the requirements of each individual place. Always have enough and to spare, as the season for sowing some crops is soon lost, and unless you make provision for failure by duplicate sowings great inconvenience, or the loss of a crop, may result. There is nothing gained by hurrying seeds into the soil when it is in a sodden or bad state, as in cold ungenial springs like the past later sowings make most rapid progress. All kinds of seeds that are sown in beds and transplanted to permanent quarters, should not, on any consideration, be allowed to get drawn or starved in the seed-beds. If the ground be not in readiness for their reception, as soon as large enough they should be pricked out in nursery beds, and carefully removed afterwards. Peas are almost universally a favourite crop, and some extra attention is necessary to have them in season as long as possible. The earliest sowings should be considerably thicker than late tall-growing kinds. I find the system of growing the late kinds in trenches decidedly an improvement on light lands, and it may also be adopted with good results for Scarlet Runners, and any crops that suffer from drought, and continue prolific according to the amount of food supply available. Mulching forms an important operation in summer cultivation, and, if done neatly, need not be at all unsightly. Strawberries, especially, are benefited by it. Some market gardeners apply it early in spring, covering the rows as well as the ground between them. There is no gain, as regards economy of labour, in neglecting neatness and order, the difference between a garden kept systematically clean, and one where "weeds run to seed," can only be appreciated by those who have tried it.

Exhausted crops should be cleared from the ground immediately, as by making surplus growth they not only rob the land to no purpose, but give an impression of dismal desola-

tion and decay which should be as much avoided in the kitchen garden as in that portion of the grounds devoted to ornamental gardening.

JAMES GROOM.

Henham.
[We doubt if a formidable series of walks, edgings, &c., are necessary in the kitchen garden at all. They are costly to form and troublesome to keep. In the best cultivated kitchen gardens we have ever seen, the only walks are alleys between well-grown crops.]

FARMERS' GARDENS.

To avoid all objections that may be made to a farmer's kitchen garden, we wish to suggest that it be located in the field, and be cultivated field-fashion, ploughed as for all other field crops, planted in long rows, and cultivated by horse power. No fence is necessary. In fact, a fence around a kitchen garden is a nuisance, occupying uselessly good land, impeding the facilities for labour, and furnishing a refuge for weeds. Besides, the garden should not occupy, continuously for a series of years, the same site. It is a great deal better that its location should be changed occasionally, so as to secure a fresh soil. By a judicious use of a variety of manures the old garden may be kept productive, but it requires more skill, and a greater outlay, than most farmers are willing to bestow upon it, to keep a garden up to the highest point of productiveness for a score of years. The Asparagus bed must have a fixed habitation, and some of the small fruits usually cultivated in the garden, such as Currants, &c., are not easily changed. The Asparagus bed we should keep on the same spot indefinitely, for the shoots from an old bed we have found, under proper culture, to be more vigorous than from a new one. We are now cropping Asparagus from the same roots which supplied the table of our progenitors. With an annual top-dressing of compost, they continue to yield bountifully. The smaller fruits might possibly, under the same treatment, continue to thrive indefinitely, but it would be necessary to cut out the old mossy stems, and bestow an amount of labour upon their cultivation, which is entirely unnecessary in the care of Asparagus. So far as our observation goes, it is more profitable to renew the roots and occasionally change the site of the fruits. And as for Melons and Vines of all kinds, Potatoes, Beets, &c., everybody knows that they flourish best on a fresh turf. With no fence around the garden, its site may as easily be changed as the site of any field crop. As to the size of a garden, this must be regulated by the size of the family, but let the supply and variety of vegetables be liberal. We once heard a young farmer say that the producers could not afford such a variety of vegetables as citizens and mechanics. This idea, we suppose, is founded on the old principle that shoemakers' wives must go bare-footed, and dairymen's families without butter and cheese. Whatever the principle, we have no hesitation in pronouncing it wrong. It is true that the tendency with most producers is to stint themselves in the consumption of their own products, as these are their resources for money, the great end of life with too many persons. There is work to be done in the garden, even under the best system of culture, but with the garden in the centre of a field, or with a border of turf between it and the boundary fence of the field, most of the work can be done by horse power, and at a quarter of the expense of the old mode of hand culture—and we are confident that if farmers will only try this mode of gardening, their prejudices against horticulture will be dissipated as is the dew in the morning sun.—"New York Times."

The True Rhubarb in England.—It will be recollected that some years ago (1867) M. Dabry, the French consul in Hankow, succeeded in obtaining living roots of the mother-plant of Rhubarb, which were sent to the Société d'Acclimatation in Paris, and, although badly injured, were brought to full development through Dr. J. L. Soubeiran. The species was determined as a new one (Rheum officinale) by Baillon. Since then the plant has been grown at other places, and, according to Professor Flüchiger, is so handsome as even to deserve a place as an ornamental plant in public parks and gardens. At Flüchiger's desire, Hanbury induced the proprietors of the great Rhubarb plantations in Bodicott, Oxfordshire (Messrs. Rufus, Usher, & Sons), to grow the new variety and prepare some for market. The result—on the small scale—has shown that careful treatment will undoubtedly produce from it Rhubarb exactly identical with the best Chinese.

Where are Lentils to be Bought?—Will you kindly inform me where in London I can obtain them?—A. X. A. [At Mr. Gaines', Covent Garden Market, who supplies both Lentils and Lentil-flour.]

THE INDOOR GARDEN.

ORCHIDS IN BLOOM AT STAMFORD HILL.

A FEW days ago I called to see Mr. Bockett's splendid collection of Orchids at Stamford Hill. Amongst other fine plants was a magnificent display of *Cattleya Mossia*, consisting of many superb varieties; some of them were almost as light-coloured as the scarce *C. Wagnerii*, and others nearly as dark as *C. labiata*. One beautiful form had a lip with a deep purple centre and pure white margin; another with immense flowers had in the lip almost equal proportions of crimson and deep orange. Of this *Cattleya* there were some 200 expanded flowers, and grouped, as they were, together at one end of the house, they had a strikingly grand effect. Standing near them were two splendid examples of *C. lobata*, bearing fourteen spikes with from five to seven flowers each. I also noticed four or five

Masdevallias, amongst which was a grand example, bearing nine spikes, of the one known amongst Orchid growers as the Bull's-blood variety (*M. Harryana sanguinea*); it may be said there is nothing in a name, but surely this is an ill-chosen name for such a magnificent flower. T. BAINES.

Griffinia ornata.—This is a beautiful, new winter-blooming, bulbous plant, from Brazil. It has elliptic-oblong leaves, the margins of which are so much recurved that a cross section would almost describe a semi-circle. The flower-scape is from 12 in. to 18 in. in height, and bears an umbel consisting of about two dozen flowers, forming a spreading head of some 8 in. or 9 in. in diameter. The flowers are of a delicate bluish-lilac fading off to nearly white, and remaining for a considerable period in beauty. Some good

Griffinia ornata.

plants of *C. Mendellii*, and several examples of *Lælia purpurata*. Associated with these were likewise *Aerides Fieldingii* and *A. Lindleyanum*, both extremely strong and vigorous; here their growth is slower, but much more satisfactory than when made in more heat. In an adjoining house were numbers of the lovely *Cypripedium niveum*, bearing some sixty flowers; *Vanda cristata*, several spikes; *Dendrobium Parishii*, *Odontoglossum citrosum*, *O. Roezli*, both the yellow and purple-eyed varieties; several plants of *Lælia purpurata*, with from seven to nine spikes each; *Saccolabium guttatum*, *Sobralia macrantha*, *Cypripedium Stonei*, *C. Hookeri*, and *C. Veitchii*. In the *Odontoglossum*-house were twenty plants of *O. Alexandro* in flower and about as many more coming on; *O. cristatum* Dayanum, twenty-three spikes; *O. Pescatorei*, *O. odoratum*, *O. navium*, *Oncidium macranthum*, very strong; *Mesospidium sanguineum*, with fifteen spikes; *Epidendrum sphygostyum*; *E. paniculatum*; also a number of fine plants of the several kinds of

examples of it may be seen in Mr. Ball's Nursery in the King's Road, Chelsea, where it is found to be easily managed and a good addition to handsome flowering bulbous plants.

BEGONIAS AND THEIR CULTURE.

AMONGST stove plants, few combine the desirable properties of a long, and in some cases almost continuous, habit of blooming, with freedom of growth, so well as the different kinds of Begonia. Indeed, their well-known character in this respect often causes them to suffer from neglect, in a way that precludes the possibility of their true worth being exemplified. They are generally grown without sufficient light in dark corners, under the shade of other plants, whereas they are essentially light-loving subjects, requiring to be kept

near the glass, with very little shade, even in the brightest weather. When otherwise treated, the leaves get too large, the shoots become unduly elongated, and the natural disposition to flower becomes reduced. From the day when the cuttings are first rooted, they require all the light that a well-constructed house or pit can afford, with a drier condition of the atmosphere than many stove plants need; but, as it seldom happens that in private establishments a separate house can be afforded them, or the atmosphere be made, as regards moisture, exactly in keeping with their requirements, the next best course is to place them as near the glass as they can be got, to shade little, and to give them as much air as is consistent with the well-being of other plants that may have to be grown along with them. In propagation, as in their after-growth, there is little difficulty, as they form roots in a few weeks; they may be struck at any time of the year when a temperature of 60° or 65° can be kept up at night. If they are inserted about the middle of March, there will be plenty of time to grow them into good plants for autumn and winter flowering, during which season they will be found most useful. The tops of moderately strong shoots make the best cuttings; but, if these cannot be got in sufficient quantities, smaller pieces will do. Cut them to a joint, retaining the latter to form the base of the cutting, with a couple of joints above. Pot them singly in 3-in. pots, with a little drainage in the bottom, half filled up with sandy peat—the remainder all sand; and do not give much water until roots are formed, only just enough to prevent the leaves from flagging. Owing to their succulent nature, if kept too wet, they are liable to rot; neither must they be kept too close under the propagating glasses. In three weeks or a month they will be well rooted; then remove them altogether from under the glasses, and place them in the lightest part of the house. They should be kept at 79° at night, and 10° higher during the day. Move them into pots 4 in. larger than those they are in. They do best in four parts good fibrous loam and one of leaf-mould or rotten manure, with enough sand to allow the water to percolate freely through it; for, although from their quick habit of growth they require an abundance of moisture at the roots, still they cannot stand anything approaching stagnant water in the soil. Stop the points of the shoots to induce them to make bushy growth, and do not shade, except during the middle of the day in very bright weather. Give plenty of air early in the morning, but economise sun-heat, by shutting up whilst the sun is upon the glass, damping the plants slightly overhead at the same time. About the end of July they will need shifting into their blooming pots. The size of these must be regulated by the more or less vigorous habit of the kinds grown. Such sorts as *B. manicata* will need much more root-room than weaker varieties, like *B. fuchsoides*. 9-in. or 10-in. pots will be large enough for such kinds as the latter, while the former should have pots 12 in. or 13 in. in diameter. Use similar soil to that into which they were last put, but do not now break it so fine; again pinch out the points of the shoots of plants that do not appear to be sufficiently furnished; and place a few sticks to train them out, so as to admit plenty of light to the centre. Do not give too much water until the roots have got hold of the soil, and treat them in other ways as recommended in the earlier part of the summer. By the middle of September they will have grown to a useful size for general purposes, as it is not desirable to grow these Begonias very large. The atmosphere should now be a little drier, and the temperature kept about 60° at night, and 6° or 8° higher during the day. Many of this family will bloom during the summer season, but for the purposes under consideration it is not well to encourage them to do so, as their flowers are of much more service in autumn and winter. Some of the old-established kinds will be found well adapted for use at this season. When the pots are full of roots they will be benefited by occasional applications of manure-water, especially during their time of flowering. When they have done blooming it is best to destroy the plants, except such as are required to provide cuttings for another year. For this purpose it is necessary to give them proper attention, for if neglected they do not make shoots suitable for growing on freely. The following sorts will answer well for autumn and winter blooming:—*B. insignis*,

B. fuchsoides, *B. manicata*, *B. Prestoniensis superba*, *B. Digswelliana*, *B. Sedeni*, *B. Ingramii*, and *B. cinnabarina*. One great recommendation belonging to Begonias, is their immunity from insects, as they are rarely affected with any of the pests to which stove plants are subject. T. BAINES.

Passion-flowers.—The notice of Passion-flowers given in your number of May 27 very much interested me. I have planted *Passiflora quadrangularis* var. *alata* in a greenhouse with a southern aspect. It has merely had the frost kept from it in winter, and the plant thrives and does wonderfully well. This has been a pleasant surprise, for there were great doubts expressed about it at first. The only thing I should add is that it has not yet blossomed quite satisfactorily. The flowers had just opened, and then they have fallen off. They appear in the early days of April, and if they could only be retarded for a few weeks I think they would do well another year. At all events, it is satisfactory to know that this plant will exist quite well under favourable circumstances out of a stove.—H. EWBANK, Ryde.

The Greenhouse Yuccas.—Of these *Y. aloifolia*, *Y. variegata* and *Y. quadricolor* are perhaps the handsomest and most generally useful. The second named is the best in these respects. *Quadricolor* is pretty, but of slower growth. Any of the three make good vase plants, but whether employed in the drawing-room, or out-of-doors, they should be placed at arm's length, for their spines stand out like an array of spear-heads. They all grow freely out-of-doors in summer, but they progress rapidly under glass, and soon make good specimens. In my particular case the plants have to be often moved about for decorative purposes, and unavoidably get their bottom leaves injured, which disfigures them. I am, therefore—inasmuch as we do not want tall Yuccas—in the habit of cutting the plants periodically and striking the tops, which are generally about 18 in. high to begin with. The old stumps are put aside to sprout, which they do readily, and I have often had more stock than I wanted. The work of cutting over and striking should, however, be performed at the proper season, which is about the beginning of April. The tops will strike with tolerable certainty at almost any season if they get heat enough, but the old stumps are apt to gangrene and die back unless they are quickly excited into growth; and this is most easily done early in summer, when they begin to grow naturally. My plan is to cut the tops off with a sharp knife, and pot them in 7-in. pots in a light compost, consisting of loam, leaf-mould, and sand, and plunge them in the Pine-bed in the full sun. They strike directly, and root so freely that they need shifting on very soon afterwards. They should be transferred to the greenhouse as soon as they are fairly established in the cutting-pot, for a warm house is not the place for them afterwards. The old stools are also better in a dry, warm corner of a greenhouse than anywhere else. They soon push numerous young shoots just below the cut, and if these be taken off when they have a bit of bottom to them, they can be struck in the same way as the tops.—CHEF.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

A Specimen Pot Rose.—In the splendid group of Pot Roses exhibited by Mr. Turner at the Royal Aquarium last month, a plant of *Paul Perras*, some 8 ft. high, was carrying 200 blooms! The history of this specimen is noteworthy as showing not only the size to which a pot Rose may be grown, but the healthful and vigorous longevity at which it may arrive when well managed. This plant was purchased ten years ago from Messrs. Lane, who had exhibited it for ten years; it has therefore been serving the purposes of exhibition for twenty years, and is yet strong and vigorous.

Blue Hydrangea Flowers.—I live in the Weald of Sussex, but I am surrounded by a great variety of soils. The Hydrangeas is always pink in clay soil, but blue in peat, which is about a foot deep on the Sussex iron ragstones. I have observed two Hydrangeas not more than 200 yards apart, one of which was blue, the other pink, the former being in the peat soil.—Correspondent "Journal of Horticulture." [Mr. Lane, of Berkhamsstead, informs us that when he pots Hydrangeas in peat, the flowers produced are blue but for one year only. In the same pots the following year the flowers are of the usual pink colour.]

Odontoglossum vexillarium.—This grand Orchid should find a place in every cool Orchid-house. I have a small plant of it here now in a pot about the size of a breakfast-cup, with sixteen blooms on one bulb, some of which measure $\frac{3}{4}$ in. by 3 in., and are of the most lovely glossy pink imaginable, with a pure white centre and yellow pencilled eye. While speaking of cool Orchids that require to be kept constantly moist at the root, I find all such as are in pots glazed outside thriving better than those that are in common porous pots, because the glazed pots retain moisture more steadily, with less frequent watering than unglazed pots. These pots would also suit many other plants that require a plentiful and steady supply of moisture.—D. THOMSON, in "The Gardener."

Panacrastrum rotundum.—This American bulb is, according to the editor of the "Gardener's Monthly," quite as handsome as many of the imported Lilies and other grand plants from abroad. It is not at all abundant in cultivation, and, practically, it has yet to be introduced.

TREES AND SHRUBS.

NEW SHRUBS AND TREES AT THE CHATEAU DE SEGREZ.

WHEN spending a day recently at the Château de Segrez I noticed the following new and rare trees and shrubs growing in that unrivalled collection, some brief account of which may not be uninteresting. Among others was the Evergreen Plane (*Platanus cuneata*), from the mountains of North America, an exceedingly rare tree in European collections, indeed Monsieur Lavallée informed me that he had never met with it or heard of it elsewhere; it was sent to him as a variety of Maple by the person who brought it from America, but this he soon discovered to be a mistake; apparently it is not quite hardy, as one of his two plants was killed last winter; the other, in a more sheltered position, was, however, wholly uninjured; in the milder parts of this country it would probably be quite hardy, and as all the other members of the family are deciduous, it will, when better known, undoubtedly prove a great acquisition, as its foliage is very ornamental. *Deringia celosioides variegata* is a beautifully variegated shrub, new to me, and one which will in all probability prove quite hardy in this country. *Euonymus angustifolius* is an uncommon shrub now covered with a profusion of curiously shaped small dull red blossoms, which give a singular appearance. *Viburnum coccineum* is considered by M. Lavallée to be one of the most valuable of its family, as it produces its pure white blossoms, followed by handsome scarlet berries, almost all the year round. *Eleagnus longipes*, also known under the name of *E. edulis*, from its producing edible fruits resembling those of a *Berberis*, is also, in his opinion, a valuable and ornamental shrub, and a variety but seldom met with in collections. In *Cratægus* the collection is exceedingly rich, but perhaps the three most remarkable varieties are an unnamed kind received from Kamskatka, very dwarf and bushy in habit, producing conspicuous large white flowers in abundance, and in the autumn handsome, brightly-coloured fruits. This M. Lavallée proposes to name *Cratægus atro-purpurea*, and considers it quite distinct from any other variety of the family. *C. stricta* is a curiously erect and pillar-like growing form of the common *White-thorn*, which I have never seen elsewhere. *C. tanacetifolia* is an exceedingly distinct and ornamental form, owing to its curiously glaucous foliage; it seems to be an abundant bloomer, and is much later in opening its flowers than most others of the family. A fine bush of the white-blooming *Ceanothus velutinus*, with thick leathery foliage, and now covered with blossom, was interesting, inasmuch as I believe the variety has been for some years lost to British gardens, at least the nurserymen who sent it to me some years ago informed me that they could no longer supply it, and I have never seen it offered by any other firm. In Philadelphia the Segrez collection is very rich, possessing no fewer than fifty-five varieties of this beautiful and usually sweet-scented flowering shrub, commonly but erroneously known as *Syringa* (the proper designation of the Lilac family), and also more appropriately as *Mock Orange*; of this large number the two best and most distinct are probably *P. hirsutus*, an exceedingly profuse bloomer, and *P. laxus*, which has the largest individual blooms of any, being at least four times the size of the variety known under the name of *grandiflorus* or *speciosissimus*, but somewhat later in opening its blooms than that variety. A very distinct and handsome Palm, recently received from Oregon by M. Lavallée under the name of *Fritchardia filamentosa*, if, as it is said, it will probably prove perfectly hardy, will be a most valuable addition to the small number of hardy Palms now in cultivation in our gardens, which do not exceed four or five varieties. W. E. G.

The Cause of Stem-bleeding in Conifers.—Is there any cure for a Mexican Pine, the sap of which is exuding from the stem; it first appears in the shape of small drops, and then forms patches which present a raw fleshy appearance. First, the ends of the new shoots die off, and then whole branches.—K. C. [The cause of this was explained in my "British Winter Garden" twenty-four years ago. Lest your correspondent cannot lay his hand upon

that book, I quote from the chapter (p. 58), which exposes the evils arising from pot-bound trees:—"I have seen Cedars of Lebanon, after growing well for several years, become unhealthy, with portions of resin oozing out of the stem, caused by the compressed vessels of the roots being unable to pass it; in most cases such plants became of a sickly yellow in their foliage, and frequently die. Thousands of such plants have been lost to the country from this cause alone. I can scarcely travel a few miles in any direction without seeing proofs of it in different stages. Some Cedars of Lebanon, which I knew near Derby upwards of twenty years ago, are not much larger than when I first saw them."—W. BARRON, *Borrowash*.]

The Chili Pine (*Araucaria imbricata*) in the Isle of Wight.—There is an *Araucaria* in this parish (St. John's, Ryde) which is not much known, but it is by far the finest I have ever seen, and all those whom I have taken to see it have expressed the same opinion. It is growing in Miss Johnson's garden at Willow Bank. I do not know that it has ever been measured with accuracy, but it certainly would seem to be about 36 ft. in height. The tree is faultlessly symmetrical, like the Irish specimen of which you gave a coloured plate (see p. 84), and it is quite feathered with branches down to the ground; I am sorry, however, to say that there are some brown leaves on it here and there. I think the soil is getting worn out, and ought to be enriched again. I should add that the tree of which I speak produces cones; this has happened several times.—E.

How to Stack Timber.—In stacking timber the following suggestions may be useful:—1. Let the "skidding" as a rule be placed as nearly as possible level both ways, and in no case allow the upper side of it to be less than 12 in. distant from the ground. It will then necessarily follow that, whether the stacking ground be level or upon the hill-side, there will be ample space for ventilation under the timber to be piled thereon. 2. Let the butt-ends of the logs be placed to the front, and keep the back or top ends of each tier slightly higher than the butts, for facility in withdrawing them from the stack. 3. Let the skidding over each tier of logs be level, and place short blocks under it as packing pieces, $1\frac{1}{2}$ in. or 2 in. in thickness, upon every log. The advantage of this is that by removing the packing pieces, any log in the tier between the two layers of skidding may be withdrawn from the stack without disturbing the remainder. 4. If the timber to be stored cannot be placed in a permanent shed, it should, with the view to its preservation, have a temporary roof placed over it. The size of the stack, therefore, should be considered in setting it out, limiting the breadth or span to 25 ft. or 30 ft. 5. Let each tier as it rises be set back 6 in. to 8 in., to enable the converter to get over it without a ladder, he will find it convenient for examining and selecting his logs for conversion.—"Laslett's Timber and Timber Trees."

Law for the Encouragement of Planting.—The law in New York State, making provision for planting shade trees along the highway is as follows: Any inhabitant liable to highway tax who shall transplant by the side of the public highway any forest shade trees or fruit trees of suitable size, shall be allowed by the overseers of highways, in abatement of his highway tax, 1 dol. for every four trees set out; but no row of Elms shall be placed nearer than 70 ft., no row of Maples or other forest trees nearer than 50 ft., except Locust, which may be set 30 ft. apart; fruit trees must also be set at least 50 ft. apart, and no allowance as before mentioned shall be made, unless such trees shall have been set out the year previous to the demand for said abatement of tax, and are living and well protected from animals at the time of such demand.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Paulownia imperialis.—This is now in bloom at Hampton Court, where there are several specimens of it. Its flowers are borne in terminal clusters, and are as large as those of a *Gloxinia*, which they resemble in form, the colour being a delicate bluish lilac. Its general appearance as seen at a distance is that of a tree enveloped in faint blue smoke.—B.

Thuja elegantissima.—This beautiful golden form of the Chinese *Arbutus*, originally sent out by Messrs. Rollison, of Tooting, has proved of greater value than most of the variegated *Conifers* introduced to gardens. It is now brought to the London market in various sizes, where it realises a good price. The presence of a plant in the flower market is, perhaps, as valuable a test of merit as any certificate.—J. H.

Trees in Trafalgar Square.—Permit me to suggest an extension of the good taste by which trees have been planted up Northumberland Avenue from the Embankment to Charing Cross, viz., that they should further be planted all round the edge of the roadway, on the curb of the pavement, of the centre part of Trafalgar Square; so that the green leaves, mingling with the view of the fountains, may relieve the colourless aridity of the extent of stonework. So writes a correspondent of the "Builder"—thus giving advice often before propounded in *The Gardener*, but improvement in the planting of street trees in London moves slowly.

TRUFFLE HUNTING AND PLANTING FOR TRUFFLES.

TRUFFLES, like caviare, are things of which many talk who never saw or tasted them; and even of those who have been lucky enough to sit down to a turkey stuffed with them, we fancy the majority have no notion how they grow or where they come from. Housekeepers, of course, know that they come in tins or capsuled bottles, from shops like Fortnum and Mason's, or Crosse and Blackwell's, and that they are about the dearest thing that can be had in the way of flavouring, but their knowledge usually ends there. People brought up in Wiltshire or Sussex, may possibly, if they were given to chatting with the labouring men, have heard the tradition—for it is now little more than a tradition—of Truffle-hunting, with dogs specially trained for the purpose, in the Oak-coppices on the edge of the Weald, or in the broad woods that stretch from Longleat to Bruton. You may still meet an old smock-frocked fellow who knows all about Truffles, and who remembers the time when people used to think they could make money by seeking for them; but the attempt has almost died out in England, and now certain parts of France are almost the only hunting grounds where this strange underground Mushroom is sought. As with other benefactors of the human race, oblivion has been the lot of him who discovered the real Truffle—"black diamond of modern gastronomy" as an enthusiastic Frenchman calls it. There is a white Truffle, a poor tasteless sham, which grows abundantly in the sands of North Africa and Syria. This Terfez, as it is called, much used still by Arabs and Syrians, was well known in Greek and Roman kitchens. Some, indeed, go so far as to think that the Mandrakes which Reuben found, and brought to Leah, and which Rachel longed for, were Terfez. However this may be, the Truffle-trade was so important in Juvenal's time, that in one of his satires he says:—"Don't trouble yourselves, you Libyans, to do any more ploughing" (North Africa was then the granary of Rome); "we shan't complain if you send us Truffles enough." But these were the Terfez, a poor kind of thing, needing to be spiced up itself, instead of being used to give an indescribably delicate flavour to that which is cooked with it.

Truffles in the Middle Ages.

In the dark ages, cookery died out like many other classical arts. Men went back to the old Homeric roast and boiled. The tradition of Truffles was only kept alive in the books of Avicenna and other Arabian physicians. But with the revival of letters came the revival of cookery as a fine art. Men read about underground tubers in the Greek and Roman writers, from Theophrastus downwards, and so they began digging and cooking. There were rival popes in those days, and they were rivals in gastronomy, as well as in other things. Avignon and Rome vied with one another, not only in eloquent anathemas, but in elegant entertainments. Provence, too, the merry land of troubadours, was also a land of good cheer; nor was the court of Burgundy, enriched by its wealthy Flemish subjects, at all behind in the matter of dainty fare. In 1438, John the Good, then holding court in Brabant, paid six livres eight sols to Jehan Chapponeel, "pour don quant nagaires il apporta à M. le duc des Truffles de Bourgogne." A little later, in Pope Nicholas the Fifth's day, the cookery-book of Coelius, a Roman epicure of the time of Trojan, was found in some abbey library. This was loud in praise of Truffles, "daughters of the earth and the gods;" and no doubt the publication of it made them still more popular among the scholars of the Renaissance. But, though popes and Italian princes ate Truffles; though Platina, and Ciccarelli, and Matthioli wrote about them; though Savonarola denounced them, urging men to beware of them, Southern France has always been their chosen home. The Black Truffle (the most highly flavoured) grows in Provence, in Poitou, in Southern Dauphiné, &c., more abundantly than elsewhere; it does, indeed, grow northward, but so sparingly that the whole produce of the Forest of Vincennes, for instance, used to be leased, about half a century ago, for between three and four pounds. Truffle-eating took a grand start in the days of the Regency—days of "petits soupers," those anticipations of our late dinners. Read about them in Brillat-Savarin, the delightful historian and anecdotist of the culinary art; to read him is almost as good as eating them *sauvés* (as they ought to be) in champagne—in which state they are as different from the dry things used in England to flavour poultry, as the wit which drops fresh from a brilliant talker's mouth is from the stale jokes of a jest-book. Pliny calls the Truffle a vitium terre, something wrong with the ground, which forms the Truffle by getting lumped into a hard mass; and he thinks to prove this by telling a story of some Roman general in Spain, who nearly had his front teeth pulled out, by getting them tightly fixed in a denarius, which was inside one of the Truffles that he was eating. "How could the coin have got there," asks the sapient naturalist, "unless the thing was just a lump of hardened earth?" Plutarch looked on them as a sort of thunder-bolt; he says,

the four elements go to the making of them—earth, air, water, and the electric fire. He may be so far right, that all the Mushroom tribe are highly nitrogenous, and that in thunder weather a great deal of nitrate of ammonia is generated. More modern theories have been that the Truffles are, like Oak-apples and the robin red-breast of the Dog-rose, the work of some gall-insect. We shall see that there is a Truffle fly; there is also a Truffle beetle; but neither of them has anything to do with the production of Truffles. Others have thought that they were mere excrescences on the roots of the trees under which they are mostly found, and have, therefore, wended the said roots as the Chinese are said to wandle oysters to make them form pearls. Mushrooms, however, they are, and nothing else, *i.e.*, vegetables of that large class which is called cryptogamous, because its members hide more or less completely their arrangements for reproducing their species. How Ferns are really propagated has only just been discovered, and how Truffles grow is still a mystery. Do they grow from spores—microscopic seeds thrown off from the tuber? Or have they, like the Fungi which grow above ground, a mycelium—a network of soft threads forming a kind of root, and capable, under favourable conditions, of throwing up a fresh crop? This mycelium preserves the germs of life for a very long time; it is the vital part of those queer-looking cakes called Mushroom-spawn; but Truffle-spawn is one of these inventions for which the world is still waiting. Rather more than 100 years ago, Bradley, who thought that Truffles might be profitably grown in England, planted them as one does Potatoes, and the same plan was tried about the same time in Germany and North Italy. No doubt Truffles did come where Truffles were sown, but not in sufficient numbers, or with sufficient certainty, to make it worth while to cultivate them in that fashion.

Truffle Hunting.

There are Truffles and Truffles. Our native species is what the French call the Summer Truffle, light inside, and with far fainter smell than the Black Truffle. Naturalists sum up almost a score of different kinds, some of them merely flavourless lumps of leather; but the King of all is the Black Truffle—skin as dark as jet and covered with big warts; inside reddish or violet-black marbled with light veins. Its smell is indescribable; there is something of Lily-of-the-Valley, something of decayed leaves, the slightest *souppçon* of musk, and a very great deal of Truffle itself. Taste it in a Périgord pie, or, better still, if you are wintering in the south of France, get a turkey stuffed with fresh Truffles, and you will know more than pages of writing could teach you. The Truffle, then, is an underground Fungus, remotely connected, therefore, with that strange freak of Nature the Earth-star (Gaster hygrometricus), which is sometimes found in England, and which used to be sold at a seedsman's in Cornhill as "the Persian Everlasting Rose." I remember, when a school-boy, often flattening my nose against the pane and reading how this marvellous Rose, when put into water, would expand, and then shrivel up again when dry. I only lately found out that the said Rose is nothing but this subterranean Fungus, whose outer coating splits into a number of rays which, when damp, lie back like the petals of a flower, but, when dried, close tightly round the central lump. The object of this strange power of expansion and contraction is that the Fungus may work itself up to the surface. The Truffle has no such power of coming to the front; if not found out and dug up it ripens and rots away. The French generally use a pig in Truffle hunting. Such lean, long-legged swine! No wonder your French friends jokingly call them *porcs de course* (racing pigs) and *cochons-levriers* (greyhound pigs). The ancients, using the Terfez which grows in sandy soil, and is, therefore, easily discoverable, needed neither pigs nor dogs; but the pig was in use, both in France and Italy, quite early in the Middle Ages. An old writer says that people noticed that both the wild boars and also the pigs, that were turned in to eat the Acorns, now and then went Truffle-hunting on their own account; and so they got the idea of making their instinct useful. In the old times they used to put a strap round the pig's neck—as the Chinese do round the necks of their fishing cormorants—to prevent them from swallowing the precious tuber; but now, the animals are so well trained that, when they have rooted out the Truffle, they never touch it, but hold up their intelligent snouts for a bit of bread or a handful of Acorns. It is the oddest sight in the world to see a Provençal peasant plodding about in an Oak copse, a lean sow following him like a dog, and "making a point" wherever her nose tells her that what her master wants is underneath. Dogs are used in some parts of France, chiefly in Burgundy, where they mostly hunt the summer Truffle. A well-trained dog costs £4. They train him by putting a Truffle into a box full of holes, burying it, and making the dog dig it out, always rewarding him for his find with a tit-bit of some kind. The breed is Italian; and during the Truffle mania, about the middle of the last century, it was introduced into England, Poland, and several parts of Germany. Many of the small

German high-mightinesses and grand-serenities fancied Truffle hunting would be great fun, and paid heavily for the dogs, whom the dutiful chroniclers of their little greatness call, in their ponderous Latin, *canes tubercario venatici*. Sussex shepherd's dogs have often been very sagacious Truffle-hunters. But, where you have to get your bread by Truffles the pig seems the most useful ally. He can dig much better than the dog in hard, stony ground. The dog gets sooner tired; his feet grow sore; and he is more liable to stray after game, if there be any. In Provence—the special home of the Truffle—the only people who use dogs are the Truffle-poachers, of whom there are a great many. I once heard of a man who used to take both pig and dog; the pig began the digging, and then the dog finished it, and taking the Truffle in his mouth, laid it at his master's feet. Human noses are seldom sharp enough to scent out the buried treasure; though there is a story of a sickly boy who kept himself and his mother by marking Truffles for his neighbours. Of course, some Truffles grow so near the surface that they make a little crack in the ground, which catches the eye of the "hunter." This is called in Provençal, *hunting à l'escarto* (by the mark). Another plan is carefully to poke down a thin iron rod where you fancy that the dying away of the Grass may be caused by the Truffle underneath having stolen all the nourishment. Your rod meets something hard; it may be a Truffle or it may be only a pebble. The last method is to watch where the Truffle fly settles or keeps fluttering about; you are pretty sure to find what you want if you mark that spot and dig down.

Truffle Markets.

The most interesting Truffle market is at Apt, a little town in the south of Vaucluse, in the very centre of the artificial Truffle grounds of which I shall speak by-and-by. Here, from the middle of November to the end of March, every Saturday, there is a crowd, and a din of chattering tongues, and a swaying among the blue blouses, such as you could not match out of France; while, if it be wet, the "Place aux truffes" looks like a chopping sea of brown, and red, and green, and blue waves, as the mass of umbrellas tosses up and down. Such higgling, too, as if life and death depended on a centime! "Marchander" is certainly a French weakness; and there's plenty of it here to make us certain that, in spite of difference of language, the Provençal is a thorough Frenchman. Well, the higgling goes on. Rich peasant proprietors bring out their stock, and battle manfully to keep up the price. Poor women, who have trudged in from leagues away with eight or ten little Truffles tied up in the corner of a handkerchief, will sometimes stand all day, on the cold stones, under the beating rain, rather than bate their price. Regraters go round, trying to pick up bargains, as towards afternoon the courage of the sellers begins to flag a little. The big purchases are generally made last; and then, carefully stored in a special fourgon, the precious wares are sent off to Carpentras. Peasants and dealers may be pretty well treated to take care of themselves; it is the amateur buyers who suffer. "Put on your boots, my dear, and walk into the market and buy us a quarter kilo, or so of Truffles," says Madame Bonnehose to her dutiful husband. "Aunt Grognon dines with us to-morrow, and I want to give her a surprise. She has no children, you know." So père Bonnehose tries his hand at marketing; and ten to one some insinuating little dealer (he shuns the wholesale folks, thinking they'll be dearer) palms off on him a worm-eaten lot, the holes neatly filled in with black earth, or sells him, as a bargain, a splendid big Truffle, made up of several little things, stuck dextrously together with clay and bits of stick, or perhaps he buys a little bagful. The edge of the bag was turned down, and the Truffles looked so black and fresh inside. So they were—those that he saw; but he didn't have the bag emptied out. The seller, a lively, pretty little woman, kept him in close talk till the money was paid—told him all about her farm and her turkeys and her husband's disagreeable relations. And so père Bonnehose gets "done," for the bottom of the bag is filled with any "kind of rubbish"—summer Truffles, caïcou (smelling like rotten cheese), pebra, (pepper-truffle, smelling of petroleum)—stained with gall-nuts or sulphate of iron. The Truffle-bag is as deceptive as the old London "Strawberry-pottle" used to be. Sham Truffles sometimes make their way to Paris, compacted of bits of bad Potato, coloured and wrapped in a layer of Truffle-earth, to give something like the right smell. The real thing is by no means appetising to look at. The man who first ate a Truffle must have been almost as bold as he who first swallowed an oyster; but, despite the unpromising appearance, there is something in the smell which appeals strongly to the instinct of the epicure. There is plenty worth seeing at Carpentras; indeed I do not know any part of Europe more full of interest than the whole of the old Comtat (patrimony of the Popes). Some of the interest is very painful. The village of Bedouin, now a great Truffle-growing place, was cruelly destroyed in the French Revolution, and 180 of its inhabitants killed, because one night a "tree of liberty" was seen

through. Suchet, afterwards a famous general, commanded the destroying party. Carpentras has its old wall and gate pretty complete. It has a triumphal arch, not a tithe so good as that grand one at Orange—for it was long built into the bishop's palace, and served as his kitchen—but recording in its bas-reliefs, as the Orange arch does, some forgotten Roman victory over invading barbarians. When you go to Carpentras, mind you see the cathedral, part dating from the tenth century, and Constantine's bridle-bit, made out of a nail of the true Cross; but be sure, too, and see the Truffle stores. Here what are not sent out fresh are preserved, either in tins or in bottles, for the sake of those who like to see what they buy. The quantity sent to Russia and America is enormous. All sorts of plans have been used for keeping them. You may have them in oil, in sugar, in brine, in vinegar. But eat them fresh if you have the chance; no preserved Truffles, least of all the dried things one sometimes sees, give more than the faintest idea of their true flavour. You feel sure, as you eat a Périgord-pie, that the Romans could not have known the real Truffle, or they would never have dreamt of spoiling it by dressing it with Garum, Asafetida, and Rue.

Planting for Truffles.

Truffles have made many a Provençal peasant rich since Joseph Talon, of the village of Les Talons, in Vaucluse, discovered some seventy years ago that if you want Truffles you must sow Acorns. He began life as a poor Truffle-hunter (rabassier), and somehow got into the habit of dropping in an Acorn wherever he took out a tuber. Finding the crop increase, he took to planting, and used to show with pride the little field in which his oldest Oaks were growing. "Ei d'aqui que sieou vengu au mounde" ("That's how I got up in the world") he would say. His son sends some twenty pounds a week to Apt market. What makes Talon's discovery such a blessing, is that want of wood was rapidly turning the whole country into a desert. Since the Revolution, everybody had cut down as much as he pleased, and planted as little. The consequence is that hill-sides which used to have good Grass, are now torn and seamed, and all the earth washed down from them by the floods of rain to which the forests used to act as a sponge. Vaucluse and its valley, and Petrarch's forest and garden, were become an oasis in the desert. The peasant hated trees, and shirked all edicts about re-planting; all he cared for was to secure right of common for his carabos, the goats that give him milk and cheese. But now that he finds money is to be made by what trees bring with them—now that he sees a patch of poor gravelly soil bought for twenty pounds, bringing in after five years a yearly income of sixty pounds—he takes quite kindly to planting. The vine-disease, too, helped on the planting of Truffle-grounds. Many an acre of stony hill-side, where the phylloxera had killed out the Vines, is now covered with dwarf Oaks, at whose roots Truffle-hunting goes on every winter. If you go up Mont Ventoux, you will pass a deal of poor starved Rye, which certainly is not worth, straw and all, £3 per acre—and this has to be halved between the owner and his tenant; you then come to slopes on which nothing grows but Wild Thyme, and Lavender, and Everlasting Flowers. But somehow it will all carry dwarf Oaks; and in time, since the taste for Truffles is not likely to die out, all these Garrigues and Galluches, as they are called, will be planted with profit to posterity, who will have the timber, as well as to the Truffle-hunters. Moreover, the climate will be improved and the floods will be less frequent and destructive. No wonder the peasant mind is going in for Truffle-grounds, when the savoury tuber brings in yearly nearly 4,000,000 francs to the little Department of Vaucluse alone. Hence, though gourmandise is not a virtue, and Truffle-selling does give rise to a deal of higgling and deception—though, moreover, Truffle-poaching is the cause of no end of quarrels (peasants set up little watch-boxes in their fields, and go about on wet nights with dark lanterns)—we may consider the Truffle a boon to the human race, and may reckon Joseph Talon among the benefactors of his species.—"All the Year Round."

Large Asparagus.—The finest Asparagus which I have ever seen has been exhibited from time to time during the present season in Mr. Savage's shop, Park Side, Knightsbridge. Observing on the 1st inst. a very fine bundle I asked to have it weighed and counted, when I found that the sixty-two heads composing the bundle weighed 14 lb. 4 oz. Probably there have been larger and heavier samples recorded, and if so, I should much like to know of them, and where they were grown.—**STRENGTH.**

The best Broccoli.—Of these, Mr. Gilbert, of Burghley, has given a list in the last April number of **THE GARDEN**. Allow me to recommend one sort in the last April number of **THE GARDEN**. We are still eating it (June 7), and more, viz. Carter's Summer Broccoli. Many of them have produced enormous heads; one brought in to-day weighed nearly 8 lb. They were sown last year about the middle of May, and I dare say even now it would not be too late to sow them.—**B. S.**

SOCIETIES AND EXHIBITIONS.

MANCHESTER HORTICULTURAL SOCIETY.

JUNE 2 TO 9.

The remark so often made by those who describe horticultural exhibitions, that "the last was the best ever held," may, for the present, be dispensed with, not only as regards metropolitan gatherings, but also most of the leading provincial ones; for, unless where there is a disposition to give undue colour to the picture, there is no disguising the fact that most of the exhibitions held at the present day are a long way inferior to those that have been seen in times gone past. That such should be the fact, so far as regards the London shows, is not to be wondered at, but we were anxious to say that this year's Manchester Exhibition, however effective as a whole, was, in individual excellence, with few exceptions, far inferior to others that have preceded it.

Orchids.—Dr. Ainsworth, Higher Broughton, showed the best sixteen plants. Conspicuous amongst them were *Saccolabium guttatum*, a magnificent example bearing three spikes, fresh and beautiful; *Vanda suavis*, with six good spikes, and flowers large and finely marked; *Cattleya Mendelli*, bearing six spikes; *Aerides crispum*, extremely fine, one of the very best, and highly fragrant of all Orchids. Good plants of *Dendrobium Wardianum* and *Phalaenopsis Luddeamanni*, the latter with fourteen spikes, and flowers unusually well coloured. Mr. J. Broom, Didsbury, who was second, had a large and finely-bloomed *Epidendrum prismatocarpum*, a very large *Cypripedium barbatum*, *Aerides Dayanum*, a brilliantly-coloured *Masdevalla Harryana*, and a large potful of *Cypripedium spectabile*, bearing six spikes. In the class of ten Orchids, Dr. Ainsworth, who was first, had even finer plants than those in his other group. There was a splendid example of Veitch's variety of *Vanda suavis*, bearing eleven large spikes, the plant being dwarf, and covered with healthy foliage down to the bottom. Associated with this were *Cattleya Warneri*, with fifteen finely-coloured, large flowers; the old but beautiful *Odontoglossum citreum* roseum, bearing a dozen large drooping panicles of delicately-coloured blooms; and *Aerides Fieldingi*, having two branched spikes each 2 ft. in length. Mr. Fildes, who was second, had a beautiful example of *Dendrobium Schröderi*, the highly-coloured *Lechi Brysiana*, and a magnificent variety of *Cattleya Mossiae*. For six Orchids Mrs. Leigh, Staleybridge, was first. Among other plants, she had a large and finely-grown example of *Aerides Dayanum*, bearing ten large spikes. Mr. Broom, who was second, had one of the finest specimens in the show, an *Aerides Lobbi*, bearing half-a-dozen splendidly-developed drooping spikes. In the nurserymen's class for Orchids, Mr. B. S. Williams was first in the principal class; he had the beautiful old *Epidendrum vitellinum majus*, *Cypripedium niveum*, *Odontoglossum nevium majus*, and the scarce *Oncidium phymatocidium*. Mr. R. S. Yates, whose plants were larger, was second; his finest examples were *Aerides Fieldingi*, *Lechi Brysiana*, and *L. purpurata*, *Odontoglossum citreum*. In the class for ten Orchids Mr. Yates was first, and also with a single specimen.

Flowering and Pine-foliaged Plants.—Mr. T. M. Shuttleworth, Howick House, Preston, was first in this class; his group, which occupied the whole end of the spacious Exhibition building, was very effective. Conspicuous amongst the blooming plants were a moderate-sized but beautifully-flowered *Aphelaxis macrantha rosea*, *Pimelea mirabilis*, large and fresh; *Statice profusa*, in fine condition; a highly-coloured *Bougainvillea*; a profusely-flowered *Dendrobium nobile*; and a fine example of *Anthurium Scherzerianum*, bearing forty large expanded flowers, and having numbers of others to open. Among the fine-foliaged subjects, he had two immense plants of *Gleichenia Splenacea* and *ruprestris*; the handsome stately *Cycas circinalis*, and *Croton undulatum*, highly coloured. Mr. E. Pilgrim, Cheltenham, was second; among his flowering plants, which were especially fresh and bright, were *Fraxinea calycina*, very highly coloured; a deeply coloured *Hedera tulipifera*, covered with healthy foliage and flowers down to the pot, a condition about which exhibitors now-a-days do not appear to be over-particular. A large and well-bloomed *Acrophyllum venosum*, and *Clerodendron Balfourii*, a complete sheet of red and white. In the same group were also a couple of Palms in beautiful condition, viz., *Geonoma Seemannii* and *Cocos Weddelliana*. Mr. H. Samson, Bowden, who was third, showed the best examples of *Allamanda grandiflora*, *Ixora coccinea*, and *Dipladenia ambalis* in the exhibition; among his fine-foliaged plants was one of the best specimens of *Alcaesia Lovii* we have ever seen. Eight stove and greenhouse plants in flower were shown by Mr. J. Rylands, Longford Hall, who was first; among his plants were a beautiful *Aphelaxis macrantha rosea* (Chilman's variety), the finest amongst all the Everlastings; the glowing *Azalea Conqueror*, and *Pimelea spectabilis* and *Hendersoni*. Mr. W. S. Schloss, who was second, had the best *Azalea* in the show, as well as good plants of *Ixora ambonyensis* and *Fraxinea confertiflora*. Mr. T. M. Shuttleworth, who was third, showed, amongst others, the intensely coloured *Dipladenia Brearleyana*, not fully open.

Azaleas.—Here, as in most other places at the present time, *Azaleas* were indifferent. People used to find fault with them for being masses of flower without any relief in the shape of foliage, but now they do not possess very much of either. In the amateurs' class for six Mr. J. H. T. Broadhurst, Prestwich, was the only exhibitor, and Mr. G. W. Yates, Messrs. T. Lazenby and Sons, York, were also the only exhibitors. Per twenty small *Azaleas*, Messrs. G. & W. Yates received a second award.

Ferns.—Mr. T. M. Shuttleworth had undoubtedly the finest and best grown collection of plants in the exhibition; they consisted of *Dicksonia antarctica*, *Cyathea medullaris*, *C. princeps*, and *C. dealbata*; *Gleichenia*

flabellata, *G. Mendelli*, and *G. semivestita*; *Davallia elegans*, and *Leucostegia immersa*. Mr. E. G. Wright, Bury, who was second, had a smaller but very beautiful group. For six *Adiantums*, Mr. Shuttleworth was first with a faultless collection. Mrs. Leech second.

Pine-foliaged Plants.—These were largely shown in the amateurs' class. Mr. Rylands, who was first in groups of eight, had a grand plant of *Dicksonia antarctica*, also *Livistona altissima*, and *Croton undulatum*, *titifolium altissimum* and *C. angustifolium* in good condition. Mr. T. H. Bailey, who was second, had a somewhat uneven collection; Mrs. Leech was third. Mr. W. A. Schloss was also awarded a third prize for a group unmistakably equal to any shown in the class. In the nurserymen's class of ten plants Mr. Cypher, Cheltenham, was first with large and well-grown plants, among which were several unusually good Palms and *Crotons*; Messrs. W. J. Caldwell & Sons were second.

New and Rare Plants.—Among exhibitors of these Mr. B. S. Williams and Messrs. Rollison were first and second in the order in which their names stand.

Miscellaneous Subjects.—Mr. R. S. Yates was awarded a prize for a collection of *Amarylids*, a similar position being assigned to Dr. Ainsworth in the amateurs' class. For ten *Dracenas*, Messrs. Rollison were first, Mr. J. Broome and Mr. R. S. Yates, being equal, second. In the amateurs' class for *Dracenas*, Mr. J. Mort, Bowden, was first, with an even well-grown half-dozen, and Mr. S. Hodgkinson second. Of *Gloxinias* there was an unusually fine display. Mr. W. Slater was first with some seedlings, bearing very large erect flowers, and having stout short leaves, in short, grown as they ought to be, but in a way too seldom seen. Mr. Corbridge was second. Messrs. Paul & Son were the only exhibitors of *Roses* in pots, but they well deserved the first prize, which was awarded them; their plants though not large were without exception, models of skilful cultivation, and covered with a profusion of fine flowers and ample foliage. The same exhibitors were also first for cut blooms. *Lilium aratum* was shown by Mr. Fildes, who had large well-flowered examples, and by Mr. J. Heywood, whose plants were not fully in bloom. *Pelargoniums* were produced in quantities and in fine condition; they consisted of show, fancy, zonal, and variegated varieties. Mr. Rylands was first in all the nurserymen's classes of flowering kinds, his plants being, as they usually are, large and beautifully flowered. Messrs. T. Lazenby & Sons were second in the show and zonal class with well-managed collections. In the amateurs' class for six show kinds, Mr. H. G. Leppock, Higher Broughton, was first. For six *Zonals* Miss Ashton took the first with a really finely-managed group, sufficiently, but not over-tied, the flowers being kept erect, to the full length of the stalks, and not pinned down in the objectionable manner often resorted to. Mr. T. M. Shuttleworth was second, and showed very large plants. On the amateurs' class for twelve hardy Ferns, the competition was very close, Mr. Shuttleworth being just won by the more than usual excellence of his *Polypodium elegantissimum* and *Asplenium marinum*. Mr. Crowe, whose plants were larger and in splendid condition, was second. In the nurserymen's class for twelve kinds Mr. Rylands was first with a faultless group, well varied, a point not always enough attended to as regards these plants. Mr. R. S. Yates was awarded first prize for *Rhododendrons*; they occupied the extreme end of a long tent, and had a very fine effect. Messrs. Lane were second, and Messrs. G. and W. Yates, third. Of Alpine and herbaceous plants Messrs. Rollison, as usual, had the best group, which consisted of plants well varied, both in form and colour. Of *Heaths* the best came from Mr. Cypher, who showed, amongst others, one of the most profusely bloomed examples of the delicate coloured *Erica florida*, that has been seen for years, also *E. ventricosa coccinea minor*, and *E. Cavendishiana*, both good. Mr. J. Rylands received an extra prize for a neat half-dozen of small healthy plants. Mr. Cypher was awarded an extra prize for a beautiful group of stove and greenhouse plants in bloom, among which were some of the best flowered examples exhibited, especially some specimens of *Hedera tulipifera* and *Fraxinoides*. Mr. Stevenson received a like award for a similar collection, and Messrs. W. & J. Birkenhead, Sale, had an extensive and varied collection of Ferns. Messrs. W. J. Caldwell & Sons showed half-a-dozen plants of the beautiful *Yucca filamentosa variegata*, and an unusually large and beautifully-grown pair of *Standard Bays*, not less than 10 ft. high and with heads almost as much through, green and healthy in foliage. Mr. Shuttleworth had a grand pair of *Tree Ferns*, consisting of the rare *Cyathea Burkei* and *Dregoi*; Mr. Williams had a pair of greenhouse Palms. Mr. Mort showed tricolor *Pelargoniums*, extraordinarily large and covered with clean healthy foliage. Messrs. Standish & Co. had a beautiful group of *Acers* and other fine-leaved plants in splendid condition; Mr. R. Smith, Worcester, showed also a similar collection, remarkable for variety and beauty of arrangement; these two groups each occupied a half-circular bed flanking the entrance to the exhibition building, and were as effective as they were interesting. Messrs. Lane furnished ten *Ivies* in pots, in such better condition than that in which these plants are generally shown. Cut flowers of stove and greenhouse plants, which were shown in boxes similar to *Roses*, and the bouquets constituted an important feature. In the nurserymen's class Messrs. Cole were, as usual, first, with such a collection as even they have rarely, if ever, equalled, including enormous bunches of *Ixoras*, *Heaths*, *Vandas*, *Aerides*, *Oncids*, the singular *Streitizia regina*, and *Nymphaea dentata* and *Devoniana*. Mr. Cypher was second with a beautiful boxful, and Messrs. Caldwell & Sons third. In the amateurs' class Mr. Shuttleworth was first; Mr. G. Smith second, and Mr. G. W. Yates third. Bouquets were shown by nurserymen in threes for balls and weddings; about three dozen were shown, and there was not an inferior one amongst

them. Messrs. Turner Brothers, of Liverpool, were first in both, with as perfect arrangements of chaste and beautiful flowers as it is possible to conceive; Mr. G. B. Todd, Heaton Norris, was second in both classes, and Mr. Cypher third. In the amateurs' class for one bouquet, the Rev. T. France, Heyhurst, was first, Mrs. Marshall second, and Mr. J. G. Adams third. Mr. Fildes showed a group of *Sarracenia*, and the singular *Darlingtonia californica*, highly coloured and otherwise in most beautiful condition.

Fruit.—Of this there was not much, but that which was shown was good. For a collection Lord Bagot was first with Black Hamburg and Duke of Buccleuch Grapes, Smooth Cayenne Pine, *Violetta Iliative* Peaches, Downton Nectarines, Keen's Australian Strawberries, a Melon, Figs, and a dish of Apples. Lord Delamere was second with Hamburg Grapes, Royal George and Early York Peaches, Elrune Nectarines, Eastnor Castle, Gilbert's Victory of Bath and Queen Emma Melons, and President Strawberries. For Black Grapes the Earl of Crawford and Boleas was first with two such bunches of Black Hamburgs as are seldom produced at this time of the year; the berries were well coloured, large hampered, and in every way excellent. Lord Delamere was second, and Mr. J. Rylands third. Among White Grapes Duke of Buccleuch, large in berry but green looking, was placed first; it was well finished considering the season; Muscats of Alexandria were second. The former was shown by Lord Crawford, the latter by Mr. W. Blinkhorn. Strawberries in pots came from Mr. E. Lever, who was first; and Mr. Rylands, who was second, both exhibitions being good.

ROYAL HORTICULTURAL SOCIETY.

JUNE 7 AND 8.

THIS exhibition, which was very effective and well arranged, took place in a large tent on the lawn. Among the more noteworthy objects were some magnificent specimens of *Odontoglossum vexillarium*, sent from Baron Rothschild's garden at Gunnersbury, and Messrs. Veitch & Sons, furnished (not for competition) a very choice group of rare plants. Mr. Bull showed fine-foliated and new and rare plants in excellent condition. Mr. Turner and Messrs. Paul & Son contributed Roses in pots and also cut blooms of Roses in good condition. Mr. Wills had new seedlings of *Dracenas*, well selected and handsome kinds. Show *Pelargoniums* came from Mr. Turner, and Mr. Watson had a good group of fancy kinds. Fruit was not well represented, but, upon the whole, the exhibition was superior to any display of the kind that has taken place here for some years past.

First Class Certificates.—These were awarded to the following new and rare plants:

Mimulus moschatus Harrisoni (Harrison & Sons, Leicester).—This is a strong-growing hybrid, the parents of which are the common Musk (*Mimulus moschatus*) and the large-flowered *Mimulus maculatus*. Its foliage, which is of a bright healthy green, is large, like that of the spotted *Mimulus*, and has a delicate perfume, like that of Musk. The plant is most floriferous, the flowers being an inch in diameter, and clear yellow spotted with brown. It is a really first-class decorative plant.

Clematis Enchantress (Cripps & Son, Tunbridge Wells).—A large and distinct variety, good in habit and bearing double white flowers, some of the petals of which are finished in the centre with delicate rose. It promises to be a useful decorative plant.

C. Venus Victrix (Cripps & Son).—Another semi-double *Clematis*, but in this case with better shaped flowers, the sepals, which are broad, being of a delicate lilac colour.

C. Duke of Connaught (Jackman).—This, which, like the last, has large double lilac flowers of good form, will be equally useful as a decorative plant.

Croton Mooreanum (Veitch & Sons).—A strong-growing variety, having broad strap-shaped leaves, from 10 in. to 12 in. in length, and profusely mottled and netted with bright golden markings on a dark green ground. It somewhat resembles *C. Weismanni* in habit, and well deserves culture as a fine-foliated stove shrub.

Gloxinia Excelsior (Veitch).—A strong-habited seedling, which may be taken as representing a new race or strain of robust and floriferous varieties, the prominent colours of which are rose, crimson, and purple.

Habrothamnus Newellii (Newell).—A seedling *Habrothamnus*, somewhat like the well-known *H. fasciculatus*, but having larger and brighter crimson flowers, borne in dense terminal clusters. As a conservatory or greenhouse climber it well deserves attention.

Echinocactus cylindricus (Roucher).—A distinct and interesting species, chiefly remarkable for a profusion of spines, which form a perfect *chapeau de frise* around the cylindrical-fluted stem, the largest being 3 in. or 4 in. in length, and strongly hooked at the apex. It is a rare plant, and one well worth culture.

Hybrid Ivy-leaf Pelargonium, Gem (George).—This is a hybrid between the common Ivy-leaf *Pelargonium* and some form of *P. zonale*. It may, perhaps, be best described as a shrubby Ivy-leaf variety, the flowers of which are well formed and of a silvery-lilac colour, the top petals having a rosy spot. Of this variety several plants were shown, and it well deserves culture as a beautiful decorative kind well suited for pot culture.

Microlepia anthriscifolia (Backhouse).—A dwarf-growing, finely-cut Fern, bearing triangular fronds from 3 in. to 6 in. in height, these being produced at intervals along a slender, creeping rhizome,

Grown in a shallow pan of peaty compost and sandstone it forms a fresh-looking, attractive object, and is a welcome addition to exotic Ferns.

Orchids.—Conspicuous amongst these were the plants of *Odontoglossum vexillarium*, from Gunnersbury, to which allusion is made above. One of them, a delicate, coloured variety, bore forty-two flowers on a single stem; the other a vivid rosy form with larger blossoms, bore thirty-six brilliant flowers on four of the finest spikes we have hitherto seen produced by this plant. Both specimens were in the best possible condition; with these came a white-flowered *Cattleya* in the way of *C. Wagneri*. Mr. B. S. Williams showed a specimen of the hardy North American *Cypripedium spectabile*—one of the most beautiful of all Lady's Slippers—bearing sixteen flowers; also large masses of *Cypripedium barbatum* and the rare *C. superbiens*, the latter bearing nine flowers. *Mastelias*, which are becoming very popular at present, were represented by many varieties of *M. Harryana*, *M. Lindeni*, and several other less conspicuous species. Mr. Hepburn, of Sidcup Place, furnished a good plant of the large-flowered *Phalenopsis* and a noble example of *Sobralia macrantha*, bearing nearly a dozen flowers. In the same group were also a well-grown *Oncidium macranthum*, bearing a long flexuose spike of golden-petaled flowers, each measuring fully 3 in. across; and a well-flowered example of the delicate, musk-scented *Dendrobium Devonianum*, bearing six spikes of white, purple-tipped flowers. Mr. Ward had a splendid specimen of *D. Falconeri*, bearing from 100 to 150 white, crimson, and gold-coloured flowers; also a good *Odontoglossum vexillarium*, with four strong spikes. Messrs. Veitch & Sons had several distinct forms of *O. Alexandræ*, *O. Pescatorei*, and *O. vexillarium*; likewise *Dendrobium crystallinum*, with golden-lipped, crimson-tipped blossoms, and the large, milk-white *D. infundibulum*; also a strong specimen of the graceful *D. Wardianum*, bearing delicate, wax-like, white, yellow, and purple-tipped flowers, 3 in. across. *Cattleyas* were represented by many forms of the clasts *C. Mendelli* and the rosy lilac-purple-lipped *C. Warneri*, and *Lechia purpurata*. Messrs. Veitch sent a splendid specimen of *Masdevalla Veitchi*, bearing four fine, rich, orange-purple-tipped flowers.

New Flowering and Fine-foliated Plants.—Mr. Bull sent half-a-dozen plants never before exhibited in England; these were *Diplazenia Regina*, a pale peach or rosy-flowered kind; *Maranta Massangana*, having dark velvety, oblong leaves, delicately veined with grey; *Zamia principis*, a graceful pinnae Cycad, with spinose petioles; *Croton Rex*, a slender variety, having twisted, bronzy green, bristly, spotted and veined with crimson and gold; *Diefenbachia Shuttleworthii*, a green-leaved species, having a silvery band down the centre of each leaf; and *Kerata-kidogamia Hilli*, a very dark green, pinnae-leaved Cycad, well adapted for contrasting with its lighter-tinted allies. In the class for twelve new plants, Mr. Bull was again first with the vivid crimson *Diplazenia Brearleyana*; *Pritchardia grandis*, one of the most noble of all Fern-leaved Palms; *Croton trilobum*, with hastate, golden-blotched foliage; *Bertolonia Van Houttei*, with velvety-green, ruby-spotted foliage; *Aralia peltoidissima*, a distinct and new species from New Guinea; *Alpinia*, a new species from *O. majestica*; *Blandfordia principis*, a grassy-leaved plant, with bell-shaped, scarlet, and yellow flowers; *Sadleria acyathoides*, a distinct and effective tree Fern well worth culture; other plants in this group were the purple-leaved *Artocarpus Cannoni*, *Dracena Goldieana*, and *Kentia Moorei*, one of the darkest and most distinct of all pinnae-leaved Palms. Mr. B. S. Williams had also a choice group, in which we noted a new *Adiantum* with reddish-tinted fronds, and *Sarracenia Williamsi*, which resembles *S. flava*, but has much larger, moose-like heads to its pitchers. Mr. Williams had also the beautiful new *Astrocarum maritimum*, a distinct fan-leaved Palm, the under sides of the leaves of which and the spinose petioles are of a silvery-colour; *Croton Williamsi*, a bright green-leaved form, splashed with creamy yellow, and others, including the delicate *Adiantum gracillimum*. Foliage plants were well represented, the first prize for twenty in 12-inch pots being awarded to Mr. W. Bull, who had splendidly grown *Crotons*, a good *Adiantum gracillimum*, *Dracena Goldieana*, the silvery-veined *Phytolentum Lindeni*, and several good *Cycads*. Mr. Wright, of Lee, Kent, was second with a smaller but well-grown group.

Groups shown for Mr. Bull's silver cups were but limited. Twelve cups were offered, and of these only four were competed for. In the nursery-men's classes Mr. Wright, of Lee, Kent, was first with *Aralia elegantissima*, *Maranta leopardina*, which has light green leaves with darker markings; the dark, purple-leaved *Artocarpus*, and other foliage plants. Mr. B. S. Williams was second; his best plant was a fresh and healthy example of *Toodea intermedia*. Mr. Legg, gardener to Mr. R.alli, was first in the amateurs' class with *Martinezia graminifera* and a splendid plant of *Alpinia*, a class for which prizes who have never before taken a prize, Mr. C. Rann, Handcross Park, Crawley, Sussex, was first with well-grown plants.

Miscellaneous Plants.—Messrs. Veitch & Sons sent a large and select group of new and rare Orchids, *Crotons*, Ferns, *Aralias*, Palms, *Gloxinias*, and other plants, the whole tastefully staged in the centre of the large tent, where they were much and deservedly admired. The new seedling *Gloxinia*, which fringed the edge of this group, were very distinct and effective, both in flower and foliage. A great number of other flowers of the new spotted *Iris* (*I. susiana*) was much admired. The flowers shown had been plucked from beds in the open air, and were very fine, some of them measuring fully 7 in. across. From the same firm came a vigorous plant of the orange-scarlet *Hæmnanthus cinnabarinus*, bearing a globular head of stellate flowers on a purplish scape, 12 in. or 14 in. in height, the foliage being oblong and of the freshest green colour imaginable. A painful of the new and distinct *Boronia elatior* was also very effective, its bright carmine, Heath-like flowers nesting among finely-cut,

dark green leaves. In this group, too, were several distinct and beautiful hybrid tuberous-rooted Begonias in brilliant condition. Among them were *B. excelso*, *B. Vesuvius*, and *B. Sedeni*, all distinct and effective kinds. Mr. Maurice Young furnished a large and attractive group of Conifers, purple-flowered Clematises, and green-leaved scarlet-berried *Acubas*, cut-leaved Japanese *Acer*, and variegated *Amalax*. Mr. B. S. Williams had also a large miscellaneous and well-arranged group, consisting of Palms, Ferns, and flowering plants in excellent condition. Mr. J. Wills showed a group of miscellaneous decorative plants, among which were several distinct tuberous-rooted Begonias, with scarlet flowers, one named *Dr. Masters* having vivid crimson blossoms. This group was tastefully fringed with common *Moneynwort*. Messrs. Veitch & Sons sent a varied group of cut-leaved Japanese Maples, some green, others bronzy purple, all varieties of *Acer dissectum*; these had as an edging a double row of the little Violet Cress (*Toposium nemorosum*). Mr. Turner exhibited a noble group of variegated and green-leaved Ivies, conical or spindle-shaped plants, in excellent condition. Mr. R. Parker showed a group of hardy flowers, among which were cut blooms of Irides of various colours, purple, blue, lilac, yellow, sulphur, and brown; also crimson-rose and flesh-tinted forms of *Pyrethrum rubrum*, backed up by hardy Ferns, Funkias, and other fine-foliaged plants. Of plants arranged for effect, Mr. Wills had the best group; Mr. Aldous also showed in this class, but his plants were too crowded. Among miscellaneous hardy plants the most strikingly conspicuous were some well-grown examples of *Saxifraga* (*Cotyledon*) *neglensis* from Mr. Kinghorn; these formed pyramids of white star-like flowers, fully 2 ft. in height. Mr. G. F. Wilson sent a fine plant (fully 6 ft. in height) of the new *Lilium Hansonii*, bearing terminal spikes of golden-yellow flowers of great substance. This plant is quite distinct from *L. avenueum*, with which it is sometimes confounded in gardens. Several large and effective stands of *Ixias*, *Sparaxis*, and *Irids* of various kinds came from Messrs. Hooper & Co. Cut Roses were furnished by Mr. Turner and Messrs. Paul & Son; and in the classes for amateurs Mr. Chard, gardener, Clarendon Park, Salisbury, had several attractive stands of mixed varieties, and filled entirely with *Maréchal Niel*—glorious blooms both as regards size and fragrance.

Fruit and Vegetables.—Grapes were represented by good clusters of Black Hamburg, the best being those from the Earl of Portsmouth's gardens, at Hurstbourne Park, Hants. Mr. Spottiswoode, Coombe Bank, Sevenoaks, had the best Black Prince, and Mr. Douglas furnished excellent clusters of Muscats and Buckland's Sweetwater; and also some good Strawberries. Mr. Blythe, Woolhampton, sent fruit of the Japanese Medlar in excellent condition. Melons were well represented, the first prizes being awarded to *Read's Scarlet-fleshed Hybrid*, and in the green-fleshed class to *Gilbert's Victory of Bath*. Mr. Miles showed a splendid boxful of a large sort of *Golden Tomatoes*, none of the *Stamford* Pines were below mediocrity. Of Cherries, Mr. Miles had excellent dishes of Black Circassian, and also some good Figs. To Mr. Pragnell was awarded Messrs. Carter & Co.'s prize, offered for four dishes of new Peas, viz., *Premium Green*, *Carter's Extra Early*, and *First Crop*. The same exhibitor also obtained Messrs. Sutton's Prizes for Peas with *William I.*, *Sutton's Emerald Gem*, *Sutton's Bijou Dwarf-wrinkled*, and *Sutton's Kingleader*.

A list of the prizes awarded on this occasion will be found in our advertising columns.

CENTRAL HORTICULTURAL SOCIETY OF FRANCE.

PARIS, MAY 29.

THE first great exhibition of flowers and plants for this year, held under the auspices of the *Société Centrale d'Horticulture de France*, took place last week in the Palais de l'Industrie, in the Champs Elysées. The exhibition occupied the whole of the ground floor of the building, and sculpture belonging to the Exhibition of the Salon (or French Academy of the Fine Arts) being distributed among the masses of plants and flowers, the effect was all that could be desired. Horticulturally, the exhibition presented many points of special interest which I shall now proceed to mention briefly. The collection of *Gloxinias* exhibited by Mons. J. Vallerand, of Asnières, near Paris, was by far the most varied and beautiful I have ever seen at any show, and were remarkable as much for the beauty, great variety, and distinctness of their colourings, and markings as for their culture, and the excellent condition in which they were shown. In the course of the morning the two most beautiful of the unnamed seedling varieties were selected by and named after the present president of the Society and his wife, *Duc and Duchesse Décazes*, the duke being the present Minister for Foreign Affairs in France, and having succeeded to the presidency of the Society on the death of the eminent botanist, Professor *Adolphe Brongniart*, at the end of last year. To this collection of *Gloxinias* was most deservedly awarded by the jury the special gold medal of honour placed at the disposal of the Society by the Municipality of the City of Paris. The other principal prizes, consisting first of two handsome pieces of china of *Sèvres* manufacture, were awarded respectively to Messrs. Savoy and Chantin, as winners of the greatest number of gold medals at this exhibition. The two special gold medals given by the Minister of Agriculture were awarded to Mr. Charles Pfersdorff, of Paris and London, for a splendid and beautifully-grown collection of extremely curious and interesting varieties of *Cactus*, *Echinocactus*, and allied species; and to Messrs. Vilmorin, Ancelet, & Co., of Paris, for a very interesting general collection of flowering and foliage plants. The special medal, given by the Prefect of the Seine, was awarded to Messrs. Croux & Fils for an interesting collection of plants. The medal presented by the lady-patronesses of the Society was awarded to Mons. Touzet

for an exceedingly interesting and well-grown collection of *Bromeliads*, so seldom seen in perfection at our London shows. The gold medal, founded by the Society in memory of one of its former presidents, the late Marshal Vaillant, and an extra large gold medal, were also awarded to Messrs. Leveque and Margottin for two large collections of tall standard Roses in pots, which were considered of equal merit; the one for culture, the other for the varieties contained in it, but neither of which would, I think, have been noticed at all at one of our London shows, where we are accustomed to such splendid specimens of culture in the form of pot Roses, with which these tall, poorly-flowered plants would not for a moment bear comparison. An interesting small collection of new succulents was shown by Mr. Pfersdorff, consisting of a most distinct and beautifully white variegated form of *Plectranthus atropurpureus*, three new species of *Echinocactus*, named *Calceyia E. cylindrica*, *E. Engelmanni*, and *E. Engelmannii* alpinum; these were awarded a second-class medal by the jury. Neither *Chalcidias* nor *Cinerarias* were at all equal, either in brilliancy of colours or size of flowers to what we are accustomed to see at our London shows from Messrs. Dobson, of Isleworth, and others. A very fine collection of herbaceous plants in pots was also shown in excellent condition, the only novelty among them being one named *Venidium calendulaeum* quite unknown to me, with glaucous waxy foliage, and flowers and habit resembling one of the *Gnizams*. The flowers seemed to be produced most abundantly, and were of a bright golden colour, well raised above the foliage, tall footstalks, and without any dark centre eye, altogether a most distinct and ornamental plant for the herbaceous border. I have since learned that this plant is an annual easily raised from seed. New herbaceous and annual plants were represented by *Silene compacta* nana, and a so-called white variety of the same plant of really dull bluish-coloured flowers and of inferior merit: an exceedingly distinct and pretty pure white form of the well-known lilac-flowering annual *Fenzlia dianthiflora*, and by *Phlox Drummondii grandiflora*, a finely coloured and large-flowered variety of this well-known species, said to come quite true from seed. One of the most interesting features of the Exhibition to lovers of trees and shrubs was a fine collection of no less than eighty varieties of Oak in small well-grown specimens in pots sent (but not for competition) by the Secretary-general of the Society, Mons. Alphonse Lavallée, from his unequalled collection at the Château de Segrez, near Breuillet, at the catalogue of which he has been working for more than ten years, and hopes to get it published before the end of this year, embracing, as it will, over 2470 varieties of hardy and ornamental shrubs, and 2210 varieties of trees, all grown on an area of not more than 75 acres in extent; this catalogue being, of its kind, quite unique, should be an immense acquisition to all lovers of hardy trees and shrubs. Unnamed seedling Pansies were exceedingly well shown by three exhibitors, grown in pots, but plunged in tastefully-arranged beds in a shady corner, where they had an extremely pleasing effect, presenting all the appearance of being actually growing in the beds, and showing an abundance of handsome, richly-coloured, and finely-formed flowers. A new seedling *Acanthus*, with handsome, deep green, shinning foliage deeply ribbed (likely to be useful for some tropical beds, with a *Pyrethrum Golden Feather* for some such) of some very bright-foliaged plant (to show it off) was shown under the name of *A. rigidus Tenoiri*, and was awarded a bronze medal by the jury. A new and distinct form of *Yucca aloifolia variegata*, with broad white bands down the centres of the leaves and a glaucous outside margin, and as yet unnamed, was awarded a silver medal by the jury. Mons. Lemoine, from Nancy, brought up a small collection of his fine, new, tuberous-rooted *Begonias*, many of them with double flowers, but they were, unfortunately, much injured and shaken in the long train journey from Nancy to Paris. W. D. G.

The American Centennial Exhibition.—Among the English exhibits is a very fine collection of green and variegated *Hollies*, hybrid *Rhododendrons* (commonly called *American plants*), handsomely-formed standards and choice assorted varieties, some of which are quite new; fine specimen standard *Portugal Laurels*, and a superb collection of Japanese *Coniferous plants*, all exceedingly beautiful and rare. These are exhibited by the well-known firm of Messrs. Veitch & Sons, of Chelsea, and Coombe Wood Nurseries, London. Mr. Court (Messrs. Veitch's representative at the Centennial Exhibition), has been very successful in being able to bring *Hollies* to this country in such good condition, with all the foliage intact; indeed, all the plants are in fine condition, and form a striking group very artistically arranged. The exhibit made by Messrs. Veitch & Sons, and which is one of the rarest and most valuable collections in the entire Horticultural Department, has been presented by them to the United States Centennial Commission as a souvenir of the Exhibition. Among them are some varieties of *Hollies*, *Rhododendrons*, and *Evergreens* quite new to this country, and the collection will, doubtless, excite great interest among horticulturists. Correspondence elsewhere published in this morning's "Ledger," shows that the valuable collection of trees and shrubs sent to the Centennial Exhibition by Messrs. Veitch, of London, has been presented to the Fairmount Park Commission. The donors gave to the British Centennial Commissioners authority to select any charitable or educational institution on which to bestow this gift, and Colonel Sandford and Professor Archer, with excellent judgment, selected the Fairmount Park Commission. So this valuable collection of plants will remain with us to be enjoyed hereafter, as it has been now, as one of the permanent adornments of the Park.—"Philadelphia Ledger."

DIED, June 5, at the Rectory, Woodstock, Oxon, aged eighty, the Rev. George William St. John, M.A., Rector of Bladon-cum-Widstock.

No. 239.]

SATURDAY, JUNE 17, 1876.

[Vol. IX.]

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

JUNE FLOWERS IN THE NORTH.

At this season, more than at any other, is the difference remarkable between gardens devoted to bedding out and those in which hardy flowers and flowering shrubs hold the chief place. It is indeed a poor art that cannot show a wealth of beauty now in this month of flowers; and even though many people are absent from their gardens at this season, yet should their gardens be made beautiful for the enjoyment of those who do remain in the country. It is now that the newly-planted Geraniums and Calceolarias look most meagre and unsatisfying, yet it is now that hardy flowers are in the very height of luxuriance, and it is now that their true lover will busy himself noting the characteristics of his favourites, and devising new schemes for coming summers. Here, in the north, we are under the influence of the most backward spring and early summer that has been known for years. Roses, which should ere this have become tolerably numerous, have hardly appeared, not at all indeed, except on sheltered walls. Moreover, the late winter was a most trying one to all vegetation. A mild open midwinter was avenged by bitter winds and severe frosts throughout the spring, with disastrous effects upon hardy plants, which had been forced on by the open weather. It is only now that we can realise the damage done as shown by the many blanks in the herbaceous borders. Among those which have wholly or in part disappeared from mine may be noted—*Dracoccephalum grandiflorum*, in which there is not a sign of life; *Funkia grandiflora*, generally hardy, is in the same condition; of *Arum crinitum*, a favourite horror of mine, only two or three plants remain; *Aquilegia cœrulea*, nearly all dead, and so is *Primula cortusoides*. Not so its very superior relative *Primula Veitchi* (generally labelled *P. cortusoides amœna*, a clumsy pseudonym), which spreads fast, and is perfectly hardy; *P. japonica* is also none the worse, and is a really fine hardy plant—we may hope for more variety in colour in this species ere long; *Giantopus puniceus* is killed to the ground, and is recovering slowly; *Narcissus Bulbocodium* has disappeared, but I fancy it is always difficult to keep. Among Roses the only loss has been *La France*; Captain Christie, which was reputed tender, has stood well. There are many blanks in the beds of Carnations and Pinks. Of those subjects which are considered tender, but which have not suffered, may be named the Lemon-scented Verbena, common Myrtle, *Desfontainea spinosa*, *Crinum capense*, *Convolvulus Cneorum*, and *Androsace lanuginosa*; the last of the Narcissi, the beautiful double Pheasant's Eye, is now in profuse beauty in the woods here. This family has been in ever-changing beauty since the first Daffodils "took the winds of March with beauty," but this double Pheasant's Eye is the only one of the family which is not spoilt by doubling; even in this, the single form is more truly beautiful. There is much interest at present in a well-disposed rock-garden. Of the many Saxifrages now in bloom, none is so purely white or so graceful as one which I obtained from Dr. Lowe (whose fine collection at Balgreen, near Edinburgh, is now dispersed), under the name of *S. geranioides*. It belongs to the palmate-leaved group, and has graceful panicles of flowers, with a corolla shaped like that of a *Saponaria*. Another good species I got in the same place under the name of *S. hispanica*, a very dwarf London Pride, with reniform-crenate leaves. The bloom is profuse, and at a little distance off has a pleasing rosy tint. *Sedum bracteatum* makes a fine turf of buffy-white, and overhanging it in fine contrast is the scarlet *Delphinium nudicaule*. *Erius alpinus* is a sheet of soft rose, *E. hispanicus*, a deeper hue, both harmonising well with a ground of *Sedum glaucum*. *Aubrietia grandiflora* begins earlier and lasts later than any other kind known to me; it is still a mass of soft lavender. When a rockwork is once well established, it requires some management to allow the plants to develop themselves properly. This should be done

by removal, not by cutting in fine specimens, for the character and beauty of dwarf plants can only be seen when they are developed into large masses. Therefore, from time to time, new spurs and valleys should be added to a rock-work whither removals of entire specimens may be made from the more crowded parts. *Primula farinosa* is a plant which is too seldom seen, but which should have a nook allotted to itself alone, and a little peat and loam shaken over the tuft when the leaves decay in autumn. The most delicately beautiful plants in the mixed border just now are the various Columbines. Of these the most brilliant is *Aquilegia truncata*, at least so the seed from which it was raised was named by Mr. Thompson, of Ipswich. It is clear scarlet and yellow, and perfectly hardy. *A. arctica* is graceful, but a more bricky red, and the other is to be preferred. *Aquilegia grandulosa*, blue and white, and *A. Whitmanni*, deep blue, are very desirable, and *A. cœrulea* is more graceful, and pale blue, but difficult to keep. *Aquilegia chrysantha* is not yet out, but promises well, and likely to be vigorous and hardy. The purest blue flower out now is *Myosotis Imperatrice Elizabeth*, which is true ultramarine; it is quite hardy, though generally seen in conservatories. Of all bedding Violas my favourite is the clear sulphur *Grievii*, which makes a lovely contrast with Blue Perfection, but it should be planted in a bed which may remain undisturbed, as it is far better the second year than the first. I think *Aquilegia truncata*, mentioned above, must be a bright form of *A. canadensis*, as I fancy the true *A. truncata* is a late flowerer; this species forms a beautiful group with *Czackia Liliastrum*. *Renealmia (Libertia) grandiflora*, a fine plant, and good for cutting, is in flower now; it increases quickly. A semi-double *Papaver bracteatum* from Miss Hope, of Wardie, is very showy, and stands better than the common form. Lupines are now very showy for back lines. These are a few of the flowers to be specially noted with a view to next season. SALMONICERS.

A DEVON WILD GARDEN.

We have a bank here possessing great natural beauty; it consists principally of wild flowers, thinly shaded with trees. It lies between the pleasure grounds—which are amply furnished with choice Conifers, Rhododendrons, and Azaleas—and an extensive Deodar glen, in which there are several hundred specimens of that Conifer of various heights up to 40 ft. or 50 ft. On the right of a winding walk running from south to north on abruptly-rising ground, the principal flowers are growing chiefly under the trees; on the left is a beautiful foreground of extensive park-like scenery, the River Culm flowing within a mile, and the Exe two miles beyond that, while the Dartmoor Hills, 25 miles or 30 miles distant, break the horizon. From the time when Winter Aconites and Snow-drops were in bloom, we have had a continual succession of flowers, consisting of Crocuses, Daffodils (single and double)—of which quantities grow in the orchards in this neighbourhood—and Wood Anemones. These I planted many years ago by cartloads. I took them up when in flower, with large turves attached to them, from a wood, in wet ground, where they abound. We have also different sorts of Hyacinths, *Orchis maculata*, Primroses, Cowslips, Periwinkles, and the Gladwyn Iris; the bright red seeds of the latter are beautiful throughout the winter and spring, and some are even still left on the expanded seed-pods. The best effect is produced by immense quantities of wild Hyacinths or Blue Bells, and the wild *Lychnis*, in contrast with double-blossomed Furze and a large quantity of the yellow *Doronicum austriacum*, which grows and spreads very freely, the colours appearing much deeper under the shade of the trees than when exposed. These are nearly past, but Columbines and Foxgloves are now in flower, and Sweet Williams are coming into that condition: the last are allowed to ripen and drop their seeds. There are also irregular masses of indigenous Ferns, such as *Lastrea Filix-mas*, *L. Filix-fœmina*, *L. dilatata*, *L. angularis*, *Scolopendrium*, &c. Of shrubs there are common Hollies, Snowberries, Mahonias, *Leycesteria*, Pampas Grass; and near the walk, *St. John's Wort*; on the left of the walk, among other trees in groups and singly, are some very fine old Oaks and Elms, Cedars of Lebanon, *Cedrus atlantica*, and Thorns both white and coloured, the whole

making a natural and beautiful display. To this bank much attention has been paid for more than twenty years; all our forced bulbs, such as Hyacinths, Tulips, Polyanthus Narcissus, N. poeticus, &c., having been annually planted there after being well ripened off; also large quantities of Snowdrops, Crocuses, and herbaceous plants. JOHN GARLAND.

Killerton, Essex.

CROTONS AND THEIR CULTIVATION.

Crotons undoubtedly rank amongst the handsomest and most useful of stove plants, and among the best of them must still be reckoned the old *C. angustifolium*. When fairly well grown and coloured, its drooping masses of fine foliage are strikingly beautiful. *C. variegatum* and *C. pictum* are also good, but they want the gracefulness of *C. angustifolium*. Among the new ones, *C. Weismanni* is perhaps the best, and we may also name *C. interruptum* as a contrast to it; both have fine leaves. As a vase plant, *C. angustifolium* is the most useful, and little plants of it in 4-in. pots are among the best of subjects for the dinner-table; I employ no plant that is more appreciated for this purpose, unless it be the handsome, drooping *Draecena Cooperi*, which has not yet been surpassed by any of the new ones of its class. Crotons are not difficult to grow, but judicious care is required to bring them to perfection, a condition indicated by good and well-coloured foliage, be the leaves broad or long, according to the variety. *C. angustifolium* is subject to red spider, like the rest of its class, and when this pest gets the better of it, it destroys its good appearance. Much depends, therefore, on keeping it free from spider, while at the same time it should be grown in a tolerably high stove temperature, and fully exposed to the sun—conditions which rather encourage the enemy; but, on the other hand, too much shade spoils the plants by turning the foliage nearly green. The finest-coloured Crotons which I ever saw were grown in a hot Pine-pit, where they never were shaded at all; here, where the plants were otherwise well cared for, the foliage was simply magnificent.

As regards cultural treatment Crotons may be propagated by means of cuttings made of the young shoots. These strike readily in a stove temperature, if covered with a bell-glass and plunged in a bed where there is a little bottom-heat; but they will strike equally well, though not quite so soon, on a shelf in the stove, if the cutting pot be plunged in another a little larger, and the cavity round the sides be filled up with Moss or soil; one cutting in a 3-in. pot is sufficient. When well rooted, they should be shifted into a slightly larger size, and the pots should be well drained; but an inch of crocks, or less, will effect this, for it is a bad plan to fill the pot half or quarter full for such subjects, merely as a precaution, as some do. Scores of plants are ruined through being over-drained in a flower-pot. It should never be forgotten that the evaporation from the sides of the pot itself is almost sufficient to dry up a ball of soil in a day, unless the pot is a very large one. The compost which suits the Croton best is one composed of loam and peat, in equal quantities, with a good sprinkling of silver or good river sand, and some well-rotted cow-manure; but those who have not these materials may employ without the least hesitation common garden soil, put through a half-inch sieve, and mixed with fine leaf-mould and sand sufficient to prevent it from binding. If the compost can be squeezed tightly by the hand when moderately moist, without binding like clay or a lump of loam, it will do; or, to be more explicit, as the inexperienced may misapprehend these terms, let the sand and mould be pretty well seen in the compost after mixing—the sand especially, as its presence is more apparent than real, owing to the difficulty of incorporating it with the particles of soil. The same, indeed, may be said of the leaf-mould, which is soon eaten up in a body of loam, and the ball of soil about the roots has quite a different appearance at the end of a year. These remarks apply to all made-up composts generally. Sand should always be freely used when any doubts exist about the compost becoming adhesive eventually. The same kind of compost suits Crotons at all stages.

Young plants may be shifted as often as they require it at any time during the summer, but good-sized plants should have a liberal shift early in spring, sufficient to last them a year, if a

continuous and good growth be expected. The plants only begin to make growth in earnest when the roots begin to fill the pot, and a second shift only checks them. The lightest part of the stove is the best place for Crotons, and, in order to have good bushes well furnished to the bottom, the plants should be lifted up clear of their neighbours on inverted pots, to give them light and air all round. As respects their general culture, they need regular and copious waterings—particularly old plants which have been frequently shifted, as the centre of the ball is apt to become too dry, and when that happens, steeping must be resorted to; cleanliness and syringings overhead during fine afternoons, together with a moist atmosphere in the house generally, must also receive attention. Exemption from mealy bug and red spider will depend upon a free use of the syringe and soft water. Hand-washing the leaves of such dense-growing sorts as *C. angustifolium* is almost out of the question, putting aside the danger of injuring them in the operation; but the brush and hand must be used if bug gets established among the shoots to any extent; and, if spider be bad, drenching the plants with water in which sulphur has been stirred, after being dissolved in milk, will arrest its ravages. A healthy growth, however, promoted by occasional liberal top-dressings, and applications of liquid manure, is the best preventive.

The Croton needs very little training, and staking is out of the question. Nothing looks better than a freely-grown, naturally-shaped bush. It is admissible, however, to tie the branches out for the sake of symmetry, and because they are apt to crowd each other disadvantageously; but more than this is unnecessary. The shoots of *C. Weismanni*, *C. angustifolium*, and others of similar habit, may be assisted in this way. These throw out their shoots, or rather branches, in bold masses, and a little regulation gives them room to develop their foliage properly. A few pieces of twisted bast run without tight tying from one limb to another, so as not to be seen, will accomplish the object perfectly well. Plants that have grown well during the summer retain their beauty through the winter. It is only necessary to reduce the supply of moisture a little at the root and overhead; but they should not be exposed to a temperature lower than 60°, and if it be kept at from 65° to 70° in mild weather, all the better. Nothing disagrees with them so much as cold, which causes the leaves to drop off, and altogether paralyses their energies for a time. To have good foliage at the end of winter, and to start the plants into growth pretty early in the season, is the way to keep Crotons thickly furnished with leaves, upon which their beauty depends. THOMAS BAINES.

A Good Fruit-tree Wash.—Insects and mildews injurious to the leaves of seedlings and root grafts can be kept in subjection or destroyed by a free use of the following combination of lime and sulphur—(it may be called the bi-sulphate of lime):—Take of quick or unslaked lime four parts, and of common flour of sulphur one part (four pounds of sulphur to one peck of lime); break up the lime in small bits, then mixing the sulphur with it in a tight vessel (iron best), pour on them enough boiling water to slake the lime to a powder; cover in the vessel close as soon as the water is poured on: this makes also a most excellent white-wash for orchard trees, and is very useful as a preventive of blight on Pear trees, to cover the wounds in the form of a paste when cutting away diseased parts; also for coating the trees in April. It may be considered as the one specific for many noxious insects and mildew in the orchard and nursery; its materials should always be ready at hand; it should be used quite fresh, as it would in time become sulphate of lime, and so lose its potency. Wherever dusting with lime is spoken of, this should be used.—This preparation should be sprinkled over the young plant, as soon as, or before, any trouble from aphides, thrips or mildew, occurs, early in the morning while the dew is on the trees.—This lime and sulphur combination is destructive to these pests in this way; firstly, by giving off sulphuric acid gas, which is deadly poison to minute life, both animal and fungoid; and the lime destroys by contact the same things, besides its presence is noxious to them; neither is it injurious to common vegetable life, except in excess, unless the lime to the foliage of evergreens. [The above is recommended by a commission of fruit growers, presided over by Professor Cyrus Thomas, State Entomologist of Illinois, and is part of a very full report, embodying advice as to the best means of fighting the insects that infest the orchards of that State.]

NOTES OF THE WEEK.

— A RICH harvest awaits any good cultivator who takes up the best of the Cactus family, and grows them for the sake of their flowers. So we thought the other day on seeing some lovely deep rosy vases borne by a very small plant of *Echinocereus procumbens*—one of the many superb flowering plants in the family.

— The bloom of the grand old collection of Ghent Azaleas in the Fulham Nurseries has been very beautiful of late—many of the specimens have been more than thirty years in the same spot. Nothing could more forcibly illustrate the value of these brilliant shrubs for town gardens than this plantation. By the way, the Ghent Azaleas have fuller and more persistent flowers than many of our own seedlings.

— The exhaustive article on Daphnes, by Mr. George Gordon, published this week, is highly suggestive of the variety and beauty to be gathered from a single family of almost neglected shrubs. It is to be hoped, in the interest of true horticulture, that skillful amateurs will some day take up such subjects as these, and do for them what has lately been so well done for various herbaceous and bulbous plants.

— There is a remarkable new *Yucca* in flower in Mr. Peacock's collection at Sudbury House, Hammersmith—*Yucca californica*, a small-leaved species, with a tall flower-stem bearing great numbers of creamy-white beautiful flowers. The leaves are glaucous, narrow, and pickle-pointed. It is growing in a cool house, but would probably prove hardy in favourable soils and situations.

— The Italian garden so called in the Botanic Gardens, Regent's Park, is done away with, and nobody will regret the disappearance of such a puerile garden. It is replaced by a nondescript arrangement for the representation of the vegetation of various warm countries—a very feeble attempt to do what is impossible in the open air in Britain. A number of Acacias and other plants here represent one aspect of vegetation only—the type usually sent to the rubbish heap by plantsmen who respect themselves and their art. In so small a garden it is unwise to attempt what may not be well done.

— The hasty persons who say that the Plane is the only tree that grows well in London, would do well to look at the beautiful Weeping Ash trees—often old and picturesque specimens—but looking quite fresh in their young green. The specimens in the Botanic Gardens in the Regent's Park and in the West-Central Squares are very fine, but the trees seem to do in all parts of London. The Weeping Yew Elm is also a very fine London tree.

— On the occasion of the great Whitsuntide Show at Manchester Mr. Bruce Findlay, curator of the Botanic Gardens there, was presented by a few friends in the neighbourhood of London, who have been in the habit of attending these exhibitions, with a very chaste silver inkstand and a pair of silver candlesticks, as a token of their appreciation of the admirable way in which the gardens and exhibitions are conducted; and of his invariable courtesy to all connected therewith.

— *CYPRIPEDIUM SEDENI* at Drumlanrig is now producing two flower-spikes, one of which is 2 ft. 8 in. high, and bears seventeen blooms; on the other spike there are thirteen blooms, and it is nearly the same in height.

— THE thirty-third Anniversary Festival of the Gardeners' Royal Benevolent Institution is to take place on Friday, the 30th inst.; the Chairman has a subscription list open, and we hear Messrs. Sutton & Sons, of Reading, have headed it with a donation of £50. Contributions in the shape of flowers and fruit for dinner-table decoration and dessert will also be welcome.

— In the southern and warmer parts of the country the *Wistaria* ought to be more frequently grown as a bush, pyramid, or low tree, as it looks very attractive when so grown, apart from the fact of flowering somewhat later than on walls. It is easy to train it into the form of a low tree, and there is a good specimen in this form in Messrs. Osborn's Fulham Nurseries.

— THERE is a dark crimson variety of the well-known *Crucianella stylosa* now in flower at Parker's Nursery, which deserves a place in collections of hardy flowers, as it is an improvement on the common form.

— THE scarlet *Delphinium of California* (*D. nudicaule*) is a far finer plant than it was supposed to be at first. It was suspected to be somewhat miffy and tender, like several other scarlet plants from the same country which have proved failures in this; but it is, on the contrary, a very hardy perennial, and comes in flower remarkably early when there is no other colour of the same kind in the

borders, and it lasts a long time in bloom. We are writing of it from observation on the sandy soils to the south of London, where it is yet in flower, though it began to blossom immediately after the last snowstorm.

— AMONG improvements and additions now being made at Drumlanrig is a new range of glass 500 ft. long and 20 ft. wide. This is to be devoted exclusively to fruit culture.

— READERS interested in rare and curious trees may like to know that a very singular one—*Asimina triloba* (the North American Custard Apple) is now in flower in the Fulham Nurseries, long the home of one of the choicest collections of trees and shrubs in the neighbourhood of London. Its flowers are exactly the colour of impressed brown Russia leather. At page 570 will be found a note from Mr. Robert Osborn on the subject.

— THE *Rhododendrons* exhibited at Manley Hall, Manchester, by Messrs. John Waterer & Sons, of Bagshot, are just now in great beauty. Upwards of fifty new and distinct varieties are exhibited which have never before appeared in Manchester, and the show altogether is an excellent one. The greatest number of visitors who have inspected it in one day is 38,000, and during Whitsuntide week upwards of 85,000 entered the Gardens.

SCARLET NONPAREILS IN JUNE.—Mr. Uphill, of Moreton, Dorset, has sent us beautiful specimens of this Apple, plump, sound, and delicately flavoured as in March, the latest month to which it generally keeps. They had been gathered from the tree eight months, and since January last have been stored in Cocoa-nut fibre.

LARGE SPECIMEN OF *GUNNERA SCABRA*.—The old tuft of this in Kew is now a remarkably striking object; the leaves are about 6 ft. high, and some of them 4 ft. through, the diameter of the specimen itself being now about 12 ft. There is provision made to give the plant plenty of water, which, combined with the advantage of a good soil on a free bottom and a sheltered position, tend to secure such a fine growth.

CLEMATIS DEVONIENSIS.—Handsome flowers of this new *Clematis*, which is a cross between *C. Jackmani* and *C. lanuginosa*, have been sent to us by Messrs. Lucombe, Pince, & Co. It is an eight-sepaled variety, closely resembling *C. lanuginosa* in habit, and is of a delicate lavender-blue colour, fully 8 in. or 9 in. in diameter. It well deserves culture, either in pots or as a graceful plant for covering rustic fences or root-work.

A GIANTIC *POLYGONUM*.—The many now interested in effective hardy plants for the open air should take a note of *Polygonum sachalinense*, which, as we write (14th June), is nearly 8 ft. high, on a sandy soil in the London district, and an imposing mass of huge Tobacco-like leaves. It is a noble subject for isolation on the Grass in the pleasure ground or for the wild garden. There is a good specimen of it in the herbaceous department at Kew. Later in the season the growth is even more remarkable.

KNIPHOPIA CAULESCENS.—The herbaceous department at Kew is now well worthy of a visit for the sake of seeing this noble hardy plant, which is quite distinct from any of its relatives hitherto grown in our gardens. In habit it resembles a free-growing *Agave*, and it has a distinct stem; it seems to produce its flowers freely, and they are large and ornamental, though perhaps not quite so showy as some of the old "flame-flowers."

HYBRID COLUMBINES.—Blossoms of a new hybrid *Columbine* have been sent to us by its raiser, Mr. J. Anderson-Henry, of Hay Lodge, Edinburgh. It is a seedling from *Aquilegia cœrulea*, crossed with the pollen of *A. chrysantha*, and is intermediate in colour between its parents. The flowers, which possess very long spurs, are fully as large as those of *A. cœrulea*, the reflexed sepals being of a delicate lavender-blue, while the central petals are sulphur-yellow. Though *Aquilegia* cross with facility, this is by far the most attractive hybrid we have seen in the group to which it belongs. The same hybrid or variety, however, occurs in London Gardens and is by some supposed to be a variety of *A. cœrulea*.

— A portrait of the late Mr. John Standish, of Ascot, has lately been suspended in the Lecture Hall of the Royal Horticultural Society at South Kensington. Few men better deserved such a testimonial from his professional brethren.

Silene pendula compacta.—This charming little hardy plant fully maintains its dwarf compact character, and is most useful for small beds or for edgings. Its pretty rose-tint flowers convert the plants into balls of colour, a condition in which they continue for a long time. The seed should be sown about the middle of August, and the young plants will be ready for removal to their winter quarters by the time the beds are ready.—D.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

THE Irises are the greatest charm of the week in the garden. They are the Orchids of the north, with charms of colour even beyond those possessed by Orchids,—grateful fragrance, and a constitution which makes them at home in the worst soils. The delicate markings and rich and beautiful hues of those now in bloom around London are marvellous in their variety, and the rich effect afforded by some kinds is most striking. Some of the growers are beginning to suppress many of the less striking intermediate varieties—and wisely, for the presence of some of the really fine forms now in bloom is sufficient to leave an impression on the observer not likely to be forgotten, whereas some of the inferior types may be passed unobserved. In the private garden, where there is room, a large bed simple in outline should be devoted to a collection of the finer Irises, from the dwarf spring kinds to the tall early summer bloomers. This bed is best by itself in the pleasure grounds, and if well prepared at first need not be disturbed for several years, so that the plants might be allowed to become thoroughly established, in which state their blooms are far finer than when seen in nurseries, where they are frequently divided. This is a very good season in which to divide and replant Irises, provided it may be done on the spot. The young roots now pushing take readily in the fresh soil, and form strong plants for next year's bloom. A singularly beautiful effect, viewed in any way or at any distance, is afforded by a large bed of the large St. Bruno's Lily, in the Wellington Nurseries, St. John's Wood. The more we see of this plant the more we are convinced that we could not have found a more valuable hardy flower for the commencement of our coloured plate series of the present year. Four Alpine plants are now in flower, among the most useful and hardy of their kind—the white *Silene alpestris*, the rosy *Saponaria ocyroides*, the yellow *Genista sagittalis*, and the blue *Veronica saxatilis*, each dwarf, handsome, and thriving on the London clay and in the London air—more need scarcely be said as to the constitution of the plants. The Blue-flowering Rush (*Aphyllanthes monspeliensis*), a plant frequently met with on the hot and stony hills of southern Europe, is also perfectly at home on the London clay. It is suited for the rougher parts of the rock garden. At least one *Panacratium* is quite hardy (*P. illyricum*), now in flower in the Regent's Park. The blue Goat's Rue (*Galega orientalis*) is a pretty tall-growing herb, and charming for the wild garden, as it will take care of itself in any hedgerow. The tufted little hoary Thyme (*Thymus lanuginosus*) is smothered in flowers; the varieties of the common Sun Rose (*Helianthemum vulgare*) are a mass of blossom; there is one beautiful climbing Everlasting Pea (*Lathyrus Sibthorpi*), and there is the large and showy *Geranium arvense*, a somewhat new and valuable kind. *Linum carabense* is a fine blue perennial flax, a desirable plant for borders. Some of the early Lilies are opening, as, for example, the *Martagon Lily* and *L. bulbiferum*. The sparkling little white *Silene quadrifida* is one of the most charming Alpine flowers among the very smallest. The true everlasting *Gnaphalium arenarium*, which ought to be in all gardens on light or free soils, is now opening its clear yellow flowers. The most stately plant of the week is *Crinum cespense*, which has been for some time in flower on the sunny side of one of the glass-houses in the Fulham nurseries. This and its varieties are superb plants, blooming from early summer till autumn, and effective from their tropical aspect among our ordinary garden vegetation. The old *Thalictrum aquilegifolium* is a pleasing flower; it is one of the plants that grow in any soil or position, and is therefore admirable for the wild garden. The following are among the plants noted during the early part of the week.—*Allium sub-hirsutum*, *Centaurea uniflora*, *Omphalodes linifolia*, *Linaria triornithophora*, *Collinsia*, *Veronica Teucrium*, and others; *Bahia lanata*, *Lasthenia glabrata*, *Leucanthemum arcticum*, *Specularia perfoliata*, *Galax aphylla*, *Dracocephalum austriacum*, *D. Ruyschianum*, *Scutellaria alpina*, *Phlomis tuberosa*, *Rheum officinale*, *Phlox pilosa* (a dwarf species: Kew), *Orchis latifolia* (very fine: rock-work Kew), *Erysimum australe* (a dwarf, bright yellow Crucifer: Kew), *Clarkia*, *Lupinus arboreus* (very handsome on wall at Kew),

Xiphion Sisyrinchium (a delicate and pretty bulbous Iris: Kew), *Hesperis matronalis*, *Ethionema grandiflorum* (very fine at Kew), *Saponaria ocyroides*, *Iris sibirica*, *I. pallida*, *I. lavigata* (very handsome: Kew), *I. graminea*, *Anthericum Liliago*, *Allium Moly*, *Hemerocallis aurantiaca*, *Dianthus glacialis* (very fine species), *Lychnis flus Jovis*, *Dianthus alpinus*, *Iris Pavonia*, and *Polemonium humile*. The lovely and distinct *Penstemon glaber*, a dwarf perennial now passing out of flower, deserves a place in all collections from the profuseness and beauty of its delicately-coloured blossoms and its dwarf habit. Lastly, the elegantly-drooping blossoms of the Sikkim Primrose are among the fairest of the season. *P. luteola*, which is also in flower, is not remarkable for beauty, and is scarcely worthy of culture.

Violas—North and South.—A paragraph appeared in THE GARDEN of last week, which, while most justly allowing that these are far more beautiful in Scotland than in England, also states that we in England never find the Pansy and Hybrid Viola refuse to thrive. If by this statement the writer means that these plants thrive throughout every part of England, it is incorrect; they do not thrive here nor hardly in any part of the Eastern Counties, nor, if I remember rightly, at Belvoir in summer. Many years ago we planted *Viola cornuta* largely, and grew many thousands of it for edging, but again and again it failed, and had to be given up; the climate was too dry for it. It is needful, however, to add that *Violas* can be grown after a fashion in many places, and the word "thrive" admits of many degrees; but those who have seen such Pansies and *Violas* as are advertised to in THE GARDEN of last week, and are grown also at Drumlanrig, Castle Kennedy, and almost generally in fact, throughout the north of England and Scotland, will agree with me that such plants can hardly be thought worth growing for summer furnishing in the drier parts of the United Kingdom. Few flowers are more beautiful or sweet than these *Violas* where they go on growing and blooming throughout the season, and few are more disappointing where one bright display of beauty in April and May is succeeded by months of flowerlessness, or burnt or withered tops. Much moisture or some shade seems essential to the continuous beauty of those beautiful Pansies and Hybrid *Violas*.—D. T. FRIS.

Pot Vines for Early Forcing.—It is an old practice, but by no means common, to grow Vines which are to fruit early in pots down the rafters while they are making their wood. In this way the buds become very prominent from the earliest stages of growth, and are as fully developed at the base of the rods as at the tops. The joints, too, are always very short. When a growth of 6 ft. is made, or the length intended for fruiting, the top may be nipped out, and any laterals well stopped. Ripening soon shows itself, and as growth gradually ceases, the laterals may be reduced piecemeal, till nothing but the stem and a leaf to each bud remains. The Vines then under the usual ripening treatment will soon go to rest, and if well exposed to the sun in August, aided by a suitable glass structure, they may be taken out perfectly matured early in September, and placed in a cool situation to rest. In October they may be started with every chance of their bearing a good crop, which will be ripe in March. I have always observed that Vines in pots are difficult to start in the autumn, when a period of absolute rest has not been allowed them after they have well ripened their wood. At a place in the west of England where I was for a number of years, pot Vines were grown largely, and fruited the season following that in which they were raised from eyes. The treatment which they received when forming their fruit-bearing wood was simple enough. When the back shelves of the Pine stoves were cleared of French Beans, the Vines were then in their largest pots, and were placed where the Beans were, and trained down under the glass over the pathways at the backs of the stoves, thus occupying space that could not be used with advantage by other plants, and the results were very satisfactory.—M. TEMPLE, Impney Hall, Worcestershire.

Red Spots and Cracking in Nectarines.—I have a warm Orchid-house, in which I have, among other stone fruits, Nectarines; some of the latter have this season got red spots upon them, which appeared during stoning; the spots increase with the fruit, and then crack open. Will any of your readers kindly tell me the cause?—J. H. ANGLER, Upper Norwood. [The red spots upon Nectarines, followed by cracking, are caused occasionally by a surfeit of water, but the disease sometimes appears even when great care has been taken to avoid over-watering; it is probable that it has its origin in the constitution of the tree; but trees affected in the way described usually outgrow the malady. There is no remedy that I know of except careful cultivation.—R.]

Grass-leaved Iris (*Iris graminea*).

Pale-flowered Iris (*Iris pallida*).

Marsh Iris (*Iris Pseud-acorus*).

Rock Soapwort (*Saponaria ocymoides*).

Illyrian Pancratium (*Pancratium illyricum*).

Double-flowered Dame's Violet (*Hesperis matronalis*, var. *flore-pleno*).

Martagon Lily and flower spike (*L. Martagon*).

Umbel-flowered Lily (*Lilium umbellatum*).

Colville's Gladiolus (*G. Colvillei*).

Dame's Violet (*Hesperis matronalis*).

Ivy Linaria (*Linaria Cymbalaria*).

Southern Baptisia (*Baptisia australis*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

GARDEN VEGETATION IN MAY.*

By JAMES McNAB, Royal Botanic Garden, Edinburgh.

The month of May has been in general very dry, with much easterly wind. A few showers fell, but none of them of that genial nature so essential for vegetation at this season of the year. During May the thermometer was seven times at or below the freezing point, indicating collectively 26°, the lowest being on the mornings of the 2nd, 3rd, 4th, 7th, 9th, and 13th, when 26°, 26°, 27°, 30°, 32°, and 25° were respectively registered; while the highest morning temperatures were on the 21st, 22nd, 27th, 28th, 29th, and 30th, when 46°, 45°, 50°, 55°, 49°, and 50° were indicated. The following Table shows the amount of frost experienced during the month of May for the last twenty-two years, from which it will be seen that May, 1855, showed the lowest markings, indicating collectively 29°, while this year 26° of frost were registered during the month. When examining the Tables for the months of May, it was remarked that, with two exceptions, frost rarely occurred after the 14th. The exceptions during the last twenty-two years were in 1872, when the last recorded frost, was on the 18th, and in 1874, on the 17th.

Year	No. of mornings the thermometer was at or below freezing point.	Degrees of Frost registered during the day from 1854 to 1876.	Year	No. of mornings the thermometer was at or below freezing point.	Degrees of Frost registered during the day from 1854 to 1876.
1854	2	4	1856	0	0
1855	9	29	1857	1	2

1865	1	1			

The foliage of the ordinary forest trees rapidly progressed during May, in consequence of the moisture in the soil, caused by the heavy rains which fell towards the end of April before the leaves were expanded. The foliage is now (31st May) well matured, with the exception of certain American forest and ornamental trees, which are always late in coming into leaf—kinds which were particularly noticed in my garden report for May, 1875. The flowering of the ordinary ornamental trees is considerably behind an average. The Common Horse Chestnut is now covered with bloom, but none of the flowers are so rich in appearance as during former years, being somewhat dingy in colour, evidently injured by the frosty nights they were subjected to during the early part of the month; the leaves likewise are far from perfect, being much injured by insects. Laburnums are blooming very freely this year, particularly those trees of the Scotch variety (*Cytisus Laburnum alpinum*) which produced no blossoms last year. Although the common White and Scarlet Hawthorns were partially in flower on the 31st of May, a full bloom cannot be expected before the middle of June.

Herbaceous plants this year are late in blooming. Many of the early-flowering species have produced few or no seed-vessels, probably owing to the frosty weather in April while the plants were in blossom. On *Cynoglossum officinale*, although it flowered abundantly during spring, and is grown here in large quantities for its fruit for Class purposes, very few developed fruits are to be found; also the *Myrrhis odorata* and *Orobanch elegans*, plants cultivated for their fruit. The Crown Imperial and *Opilips*, whose barrenness can also be attributed to the numerous frosts which occurred during the month of April, when these plants were in flower.

On the 31st of May 232 species and varieties of dwarf Alpine and herbaceous plants (exclusive of duplicates) were counted in flower in the rock garden, the most conspicuous for colour and rarity being:—

<i>Achillea Clavacea</i>	<i>Erinus albus</i>	<i>Pentstemon Menziesii</i>
<i>Andromeda fastigiata</i>	" <i>hispanicus</i>	<i>Perovskia angustifolia</i>
<i>Draba tetragona</i>	<i>Erodium Richardi</i>	<i>Phlox Nelsoni</i>
<i>Anemone palmata</i>	<i>Erysimum helveticum</i>	" <i>setacea violacea</i>
<i>Anthyllis Erinacea</i>	<i>Fritillaria kamschatica</i>	<i>Primula cortusoides</i>
<i>Arenaria purpurea</i>	<i>Genium verna</i>	" <i>amara</i>
<i>Aubretia of sorts</i>	<i>Giobularia trichosantha</i>	" <i>lutola</i>
<i>Cactaria villosa</i>	<i>Irish cristata</i>	<i>Saxifraga of sorts</i>
<i>Campanula foliata</i>	<i>Ledum buxifolium</i>	<i>Symplocandra Warneri</i>
<i>Delphinium nudicaule</i>	<i>Lychnis viscaria</i>	<i>Thalictrum aquilegifolium</i>
<i>Draba tridentata</i>	<i>Lupospermum fruticosum</i>	" <i>roseum</i>
<i>Dryas Drummondii</i>	" <i>sum</i>	<i>Trifolium alpinum</i>
<i>Erinus australis nana</i>	<i>Menziesia Drummondii</i>	" <i>aniflorum</i>
<i>Erinus alpinus</i>	<i>Myosotis alpestris</i>	

* Read before the Botanical Society of Edinburgh, June 8, 1876.

Garden Crocuflores.—Amongst the white-flowered Ranunculuses two of the most desirable are *R. Seguirei*, from the Dolomite country, and *R. platanifolius*, which also came to me from the same locality. They have each large, pure white flowers, but the former has very dwarf-growth leaves, which remind one of a *Sidalcea*, and seldom more than two flowers on a stem. *R. platanifolius* has a tall, branching, many-flowered stem. Its leaves resemble those of *R. acutifolius*, but are larger and more deeply divided. I never saw the single form of the true *R. acutifolius*. *R. fernalefolius* is one of the prettiest of the yellow-flowered species, both as regards foliage and flower. I procured it several years ago from Mr. Wheeler, of Warminster, who had then a fine stock of it. *R. cortusaeifolius* also makes a handsome pot-plant; it is not hardy here, and has to be kept in a pit, but I have seen it growing luxuriantly in the open border in Derbyshire.—H. HARPER CREWE, *The Rectory, Drayton-Beauchamp, Tring.*

The Welsh Poppy in the Wild Garden.—For the wild garden or wilderness this Poppy (*Meconopsis cambrica*) is one of the most suitable of plants, and at the same time one of the most charming. It is a cheerful plant to look at in all seasons; perched on some old dry wall its masses of pinnately-cut foliage are very refreshing in appearance, but when loaded with a profusion of large orange-yellow blossoms the plant as a whole is strikingly handsome; it is a determined coliciser, ready to hold its own under the most adverse circumstances. Its home is the wall, the rock, and the ruin! It even surpasses the Wallflower in adapting itself to strange, out-of-the-way places, and it is worse to eradicate than a *Dandelion* or a *Dock*; it will spring up in the gravel walk under one's feet, and seems quite happy among the boulders in the courtyard. It looks down on one from crevices in brick walls, from chinks where one could scarcely introduce a knife-blade, and after all it delights most in shady places. No plant can be better adapted for naturalising on rough stony banks, old quarries, gravel pits, dead walls, and similar places, and its large handsome flowers will lend a charm to the most uninteresting situations.—THOS. WILLIAMS, *Bath Lodge, Ormskirk.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Lord Lyon Pink.—This beautiful Pink is just now coming into flower, and in colour and quality is excelled by none. Its flowers, which are deep rose red, are perfectly double and round, and the petals smooth. It is most useful in a cut state for button-holes or for bouquets, and makes a capital border plant.—A. D.

Clematis montana.—This strong-growing white-flowered species is now in beautiful condition at Hampton Court, where it is used with excellent effect on walls, associated with Ivy. It is the best of the hardy spring-flowering kinds.—V.

Christmas Roses Seeding.—A doubt expressed by Miss Hope whether Christmas Roses ever ripened seed in this country, caused me to examine some plants yesterday. I succeeded in collecting some ripe seeds of *Helleborus niger*, though by far the greater part of the pods were barren. I have not yet found any ripe seed on *H. niger maximum*.—SILKINGTONS.

The Hardy Palm in Flower.—The two large Palms growing in the open ground here, and exposed to all weathers, are now finely in flower. Each plant is bearing nine spikes of bloom, all of which are 2 ft. in length, and with stems as thick as one's wrist. The plants are 10 ft. and 11 ft. high respectively, with leaves from 2½ ft. to 3 ft. in width.—W. WILDSMITH, *Heckfield House.*

The Wild Garden by the Water-side.—In the article on this subject last week there was a clerical error which destroyed the meaning. The following sentence should read as here printed: "The juxtaposition of plants inhabiting different situations—water-plants, water-side plants, and land-plants, thriving in moist ground—would present what would, in many cases, be so undesirable—a general admixture of the whole." Also, "Near the various Irises that love the water-side might be planted those that thrive in moist ground—and they are many, including the most beautiful kinds." Meaning that in addition to the water-side species of Irises such as *I. Pseud-acorus* and *I. ochroleuca*, the finer border Irises might be planted near.

Evergreen Trumpet Honeysuckle (*Lonicera sempervirens*).—This is one of the most precious of all hardy climbers, and one unrivalled for training over rustic porches, trellises, or fences so common in country districts. Planted in a deep rich soil in a warm sunny situation it flowers all the summer, and is one of the most beautiful of all the species, producing great terminal trusses of vivid orange-scarlet flowers. I have *Wistaria sinensis*, *Clematis montana*, *Common Ivy*, and this Honeysuckle, trained together over a trellis in front of my house, and these are gay from April when the *Wistaria* commences to bloom until August or September, when *Clematis Jackmani* succeeds the scarlet Honeysuckle. At Kew this Honeysuckle is grown in the greenhouse and is there very attractive, but I find it to be quite hardy.—B.

Fuchsias for Arches.—The Fuchsia is at home trained over an arch in any glass house; each branch is then brought by the weight of its blossoms to display its beauty in the most effective way. No plants are more effective as arches than Fuchsias properly managed. By stopping the shoots at different heights, and training them over with some care, the entire arch may be wreathed all round with almost an equal amount of beauty. It is surprising that the Fuchsia is so seldom used for this purpose. A glass arch for this purpose with Fuchsias would prove a charming addition to many gardens, costing little to plant and less to cultivate.—D. T. FRIS.

TREES AND SHRUBS.

THE DAPHNES.

By GEORGE GORDON.

The genus *Daphne* is composed entirely of under shrubs, mostly with very fragrant flowers, and either evergreen or deciduous. They are chiefly natives of Europe, but the cooler parts of Asia, including China and Japan, also produce members of the family. In cultivation, *Daphnes* do best when shaded in summer from the mid-day sun, and in winter screened from cold, cutting winds, and if further protected and manured by the fallen leaves of the forest trees, they will grow with a luxuriance that we can scarcely hope to witness in our gardens under ordinary treatment. Some kinds will also grow under the drip of trees, where few other shrubs would succeed; but, as all of them have but few roots, they require to be transplanted when young. The great art in managing them, however, is never to overcharge their roots with water, or let them become very dry in summer. The soil best suited for most of the species is a mixture of loam and decayed leaves, to which a liberal quantity of old road sand has been added; none of the *Daphnes* require a rich soil, and some of them even prefer old road-sand alone to any other, and will only thrive in such a soil: this is especially the case with the Mezereon.

The different species of *Daphne* are best propagated by seeds, when such can be obtained; but they are all readily increased either by layering or by cuttings of the half-ripened shoots, or by grafting upon the common Spurge Laurel or Mezereon, according to the nature of the species to be increased; the deciduous kinds succeed best on the Mezereon, and the evergreen ones on the Spurge Laurel.

In the following arrangement I have placed the different species into sections, so that if any one of the kinds in a section be known, it will form a guide, and give an idea of what the others in that division are like: for the nomenclature of the genus at the present time is in a very confused state, both in catalogues and gardens, evidently from the fact of botanists and the compilers of catalogues never having thoroughly examined or compared the different kinds in a living state; for not only are there mistakes in the names given to the different species or varieties, but many plants also are confused under the same name.

Section I.—The Broad-leaved Spurge Laurels.

1. *Daphne Laureola* (The common Spurge or Wood Laurel) L. [Synonym—*Thymelæa Laureola*, Scopoli.]—The Wood Laurel forms a dense evergreen bush, from 3 to 4 ft. high, with large, thick, glossy, dark green, obovate-lanceolate leaves, disposed in tufts at the ends of the branches; the flowers are produced in axillary, simple, drooping clusters of five, yellowish-green and shorter than the leaves. They appear in mild seasons, soon after Christmas, and continue until March, when they are succeeded by oval berries, green at first, but black when ripe, at which time they form a favourite food with the robin, and other small singing birds. The Spurge Laurel is not only a native of Britain, but of most other parts of Europe in woods, and consequently thrives best in the shade; it will grow under the drip of trees, where few other shrubs would, and, although not showy in its flowers, is a valuable plant for a shrubbery, from its being evergreen, and having thick, glossy leaves, disposed in tufts at the ends of the branches, which become almost black, if fully exposed to the sun. There is a variegated variety of the Wood Laurel, which has the leaves more or less margined with pale yellowish-white.

2. *Daphne ponicica* (The Pontic Spurge Laurel), L. [Synonyms—*Thymelæa ponicica*, Tournefort; *Daphne caucasica*, Hartweg.]—The Pontic *Daphne* has large, obovate-lanceolate, glabrous leaves, somewhat resembling those of the Lemon, especially in the colour, but much smaller; the flowers are yellowish-green, glabrous, and in many-flowered, upright clusters, each of the long, slender stalks bearing two flowers, the lobes of which are long and reflexed; the bloom is very fragrant in the evening, and is produced in April and May. It forms a large, spreading bush from 4 ft. to 5 ft. high, clothed with rather distant, broad, glossy, light green leaves, which are more oval and shorter than those of the common Spurge Laurel. The *Daphne ponicica* is a native of Asia Minor, Greece, and Italy, and, according to Pallas, is found in Siberia in thick woods and in valleys which occur between the ridges of lofty mountains. Tourne-

fort first discovered it on the coast of the Black Sea. There is a pretty variegated kind, which has the edges of the leaves more or less margined with pale yellow or white.

3. *Daphne odora* (The Sweet-scented Chinese Spurge Laurel) Thunberg. [Synonyms—*D. indica*, Linnaeus; *D. alba*, Hort.; *D. odora alba*, French gardens; *Daphnopsis indica*, Von Martius.]—The leaves of this species are about 3 in. long and 1 in. broad, evergreen, broadly-lanceolate, thin, glabrous, somewhat resembling those of the Pontic *Daphne*. The branches are glabrous, thickly beset with leaves; and the flowers, which are disposed in terminal clusters, are sessile, remarkably sweet-scented, and, when in the bud, of a pink colour on the inside, but after expansion are pink only on the outside, the petals being white within. This kind forms a somewhat erect shrub, about 3 ft. high, very similar to the Pontic *Daphne* in general appearance, and produces its large terminal clusters of fragrant flowers from December to March. It is a native of China and Japan, and more or less tender. There are the following varieties, viz.:—*Daphne odora foliis variegatis*, Hort. [Synonyms—*D. odora marginatis*, Hort.; *D. indica foliis marginatis*, Hort.; *D. l. variegata*, Hort.] This kind has its leaves more or less margined, with a band of a yellowish-white colour. *Daphne odora rubra*, D. Don. [Synonyms—*D. odora rosea*, French Gardens; *D. indica rubra*, Hort.; *D. pontica rubra*, Hort.]—This beautiful variety has glossy, bright green leaves, which are longer, narrower, and more lanceolate than those of the species, and with the flowers of a deep red in the bud state, but when fully expanded of a deep pink colour internally. It was found by Dr. Siebold in Japan, and flowers from December to March. There is a fine variegated form of this variety, also from the Japanese gardens, with the leaves beautifully margined with yellowish-white.

4. *Daphne hybrida* (The Dauphin's *Daphne*) Sweet. [Synonyms—*D. Dauphinia*, French Gardens; *D. Delphin*, Loddiges; *D. Danphine*, French Gardens.]—The leaves of this kind are from 2 to 2½ in. long and nearly ¼ in. broad, oblong-elliptic, persistent, alternate, dark glossy green above, pale beneath, and when young thinly ciliated and with a few scattered hairs along the mid-rib and under side; the shoots are more or less hairy, stout, and of a green colour when young, but quite smooth when fully matured, and of a brown colour; the flowers are in terminal groups, nearly stalkless, of a reddish-purple, delightfully fragrant, and thickly covered on the outside with white silky hairs, which give the flowers quite a silky appearance when young. The Dauphin's *Daphne* is a very free-growing kind, which attains a height of 3 ft., and blooms early in the spring. It is tolerably hardy under favourable circumstances, but requires protection in severe winters, and is best treated as a frame or half-hardy shrub on account of its flowering so early in the season. It is a hybrid production, raised in 1823 by M. Fion, a florist near Paris, between *Daphne odora* and *Daphne collina*. The *Daphne Blegayana*, of the Belgian Nurseries, is very like *Daphne hybrida* in leaf and habit of growth, with tubular flowers in terminal clusters, and is probably only a hybrid from the same parentage.

Section II.—The Hill *Daphnes*.

5. *Daphne collina* (The Hill or Box-leaved *Daphne*), Tournefort. [Synonyms—*D. collina latifolia*, Osborn; *D. buxifolia*, Vahl.]—The leaves of this species are about 1 in. long and from 5 to 6 lines broad, obovate, alternate, and much resemble in shape and size those of the Balearic Box, with the upper surface glabrous and of a dark glossy green, while the under one is hirsutely villose. The flowers are sessile, in close terminal groups, and of a light lilac or pinkish colour, with the tubes rather broad and densely coated externally with silky white hairs, which give the tubes a silvery appearance, while the upper faces of the lobes of the flowers are quite smooth. This kind forms a beautiful, low, dense, evergreen shrub, the branches of which always take a more or less upright direction, and form a level head, covered with groups of pale Lilac flowers from February to May. The Hill *Daphne* is a native of Greece, Crete, and Italy, and grows from 2 ft. to 3 ft. in height, and is quite hardy.

6. *Daphne australis* (The Olive-leaved Hill *Daphne*), Cyrillo. [Synonyms—*D. collina*, Tenore, not Tournefort; *D. c. sericea*, Loudon; *D. c. angustifolia*, Noisette; *D. oleostolia*, Lamarck; *D. sericea*, Vahl.]—The leaves of this kind are from 1½ in. to 1½ in. long, and four lines broad, lanceolate, bluntish towards the points, and tapering much to the base, glabrous above, villose or silky beneath, and much longer than those of *D. collina*; flowers, light purple, numerous, terminal, aggregate, sessile and villose externally, with the lobes of the calyx obtuse, pale purple, and glabrous on the upper face. Professor Tenore, of Naples, considers this kind to be only a variety of Sir James E. Smith's *Daphne collina*, but it differs so much in general appearance, and is besides reproduced from seed, that it certainly is as much entitled to be considered a species, as others

similarly placed in botanical publications. It differs from *D. collina* in its much longer and narrower leaves, and in its more loose habit of growth, and greater number of flowers in each cluster. The *Daphne australis* forms an evergreen bush from 2 ft. to 3 ft. high, and is found in damp, sandy, or marshy coppices, which border the lagoons and lower shores of the coast of Naples, and, according to Mr. Strangway, is plentiful on the banks of the Lake of Licola, and of the River Voltorno and plain of South Agata, all near Naples, where it produces its very fragrant flowers in spring and autumn. This kind is perfectly hardy in England, but like all the species of *Daphne*, suffers from extreme drought in summer, although it will stand a great deal of heat if planted in light, sandy soil, and partially shaded from the mid-day sun.

Sub-section consisting of Hybrids of Daphne collina.

Many of the *Daphnes* intermix freely, and consequently some good hybrids, especially in this section, have been raised in the neighbourhood of Paris, among which the following are the most distinct and desirable:—

7. *Daphne neapolitana* (The Neapolitan *Daphne*) *Loddiges*. [Synonym—*D. collina neapolitana*, *Lindley*.]—The Neapolitan *Daphne* is a hybrid between *Daphne australis* and *Daphne oleoides*, raised at Naples several years ago, and first introduced by Messrs. Loddiges, of Hackney. It is quite hardy, grows freely, and is very fragrant. The leaves of the Neapolitan *Daphne* are from 1 in. to 1½ in. long and 3 lines broad, oblong-lanceolate, tapering much towards the base, and somewhat rounded at the point, dark glossy green above, pale beneath, ciliated when very young, but otherwise quite smooth on both surfaces; the young shoots are furnished with a short, white, downy covering, which becomes brown on the adult ones; the flowers are in terminal clusters, and of a reddish-purple colour, with long, slender tubes thickly covered externally with short, silky hairs, but quite glabrous on the upper surface of the lobes of the calyx. This handsome kind forms a dense, spreading evergreen bush, from 2 ft. to 3 ft. high, which is covered with its numerous terminal clusters of fragrant flowers from March to May. The *Daphne Delahayana* of the nurseries seems in no way to differ from the Neapolitan, and, like that kind, is a hybrid of the same parentage, raised by M. Fion, near Paris.

8. *Daphne Fioniana* (Fion's hybrid *Daphne*), *Hort.*—The leaves of this kind are from 1 in. to 1½ in. long and 3 lines broad, obovate-lanceolate, tapering much towards the base, glabrous on both surfaces, and very similar in appearance to those of *Daphne oleoides*, except that they are rather broader and quite rounded at the ends. The flowers are produced in terminal clusters, composed generally of small heads, containing five very fragrant flowers in each, which are of a pale lilac colour, with the tubes densely covered externally with short, silvery hairs, and the face quite smooth. This beautiful shrub flowers from March to May, is quite hardy about London, and bears a great resemblance to the *Daphne neapolitana* in its flowers and habit of growth. The *Daphne Fioniana* is a hybrid between *D. collina* and *D. oleoides*, raised by M. Fion, near Paris, and forms a dense, twiggly, evergreen bush, 3 ft. high, the very young shoots of which are quite hairy, while the old ones are smooth.

9. *D. Daphne collina-axillaris*, *Jacques*.—This kind is a cross between the common *D. Mezereum* and *D. collina*, obtained by M. Jacques, near Paris. It bears the habit of the Hill *Daphne*, its male parent, but produces its flowers in the axils of the leaves, like its female parent, and is decidedly very distinct from any of the other hybrids of the *D. collina* section. It flowers rather early in the spring, if protected from the severity of the weather.

Section III.—The Olive-like Daphnes.

10. *Daphne oleoides* (The Olive-like *Daphne*) *Linnaeus*. [Synonyms—*D. collina*, *Loudon*; *D. salicifolia*, *Lamarck*; *D. oleosifolia*, *Hort.*; *D. glandulosa*, *Bertolini*; *D. cretica*, *Hort.*; *D. angustifolia*, *French Gardens*; *D. Gnidioides*, *Schraeder*.]—The leaves of this species are from 1 in. to 1½ in. long and 3 lines broad, lanceolate, light green, persistent, glabrous on all parts, and furnished with a minute point or mucro; the flowers are white slightly stained with lilac, especially when in the bud state, terminal, sessile, five or more together closely surrounded by leaves, and produced at various times in the year, but mostly in July and August. It is a native of Sicily, Crete, Italy, France, and Greece, where it forms a neat evergreen bush from 2 ft. to 3 ft. high, but less showy than many of the other kinds, on account of its flowers being white and in small clusters. Introduced in 1815. There is a variety of this species with variegated leaves.

Section IV.—The Garland Daphnes.

11. *Daphne Cneorum* (The Trailing Garland *Daphne*) *Linnaeus*.—The leaves of this elegant shrub are ½ in. long and 1½ line broad, linear-lanceolate, glabrous, mucronate, persistent, and thickly set upon the young shoots; the flowers are rather small, in terminal aggregate umbels or groups, sometimes twenty in number, sessile, reddish-pink, very fragrant, and smooth on the upper side, but with the tubes thickly covered with short, silky, white hairs, externally and closely surrounded by the leaves; the berries are white and globose. The Trailing or Garland *Daphne* seldom grows more than from 9 in. to 12 in. high, but forms a most beautiful trailing evergreen, which produces its charming, bright pink flowers in April and September in great abundance. It is a native of Austria, Switzerland, Hungary, France, Etruria, and Germany; first introduced in 1752, and is one of those small shrubs which will repay any extra trouble bestowed upon it, for its flowers are beautiful, and its perfume delightful. If the Garland *Daphne* be carefully trained along the ground, it may be made to cover much more than is commonly allowed for the branches which radiate from the centre of the plant, and thus be made to breathe forth fragrance to fill the gales of April and September with delight. There are the following varieties:—*Daphne Cneorum argenteum* (the Silvery-leaved Garland *Daphne*) *Loddiges*. [Synonym—*D. Cneorum elegantissimum*, *Hort.*]—The leaves of this variety are margined with a silvery whiteness, which gives the plant a very elegant appearance. *Daphne Cneorum aureum* (The Golden-leaved Garland *Daphne*), *Hort.* [Synonyms—*D. Cneorum lutetum*, *Hort.*; *D. C. variegatum*, *Knights*; *D. C. foliolum*, *Belgian Gardens*.]—The leaves of this variety have a narrow yellow edging or band round the leaves. *Daphne Cneorum flore-albo* (The White-flowered Garland *Daphne*), *Loudon*. [Synonym—*D. Cneorum album*, *Hort.*]—This variety only differs from the common form of the plant in having white flowers, which become slightly tinged with pink before they fade.

12. *Daphne Cneorum maximum*, *Jacques*. [Synonyms—*D. Cneorum grandiflorum*, *Loddiges*; *D. C. pyramidalis*, *Makoy*; *D. C. strictum*, *Hort.*]—The adult leaves of this kind are from 1 in. to 1½ in. long, and 3 lines broad, subspatulate, rounded at the ends, and regularly tapering to the base, sessile, glabrous on both surfaces, mucronate, persistent, and much larger and longer than those of the Garland *Daphne*, while the young leaves, like the young shoots, are more or less hairy, especially round the edges. The flowers are in small, terminal, aggregate, sessile clusters, pale rose, very fragrant, and smooth on the upper surface, but with the tubes densely covered externally with silky, white hairs, which give them quite a silvery appearance. The upright habit of growth slender, twiggly, forked branches, subspatulate leaves, and pale rose-coloured flowers, with silky, white tubes, at once distinguish this kind from the *Daphne Cneorum* and all others. It is a hybrid production raised by M. Jacques, of Paris, between *Daphne collina* and *D. Cneorum*, the latter being its female parent, and like it when in a luxuriant state; flowers twice a year, namely in April and September. This kind is quite hardy, and forms an evergreen bush 2 ft. high, which, if kept in the greenhouse, will flower through the autumn and winter months.

13. *Daphne striata* (The Striped-calyc'd Garland *Daphne*) *Trattinnik*. [Synonym—*D. Cneorum* var., *Schraeder*.]—The leaves of the Striped *Daphne* are from 1 in. to 1½ in. long and 3 lines broad in the widest part, subspatulate, linear, mucronate, sessile, glabrous, and persistent; branches slender, straggling, and much divided; flowers terminal, aggregate, quite glabrous, and of a purplish colour, with the lobes of the calyx acute and the tubesslightly streaked externally. This kind bears some resemblance to the *Daphne Cneorum*, but is at once distinguished by its larger subspatulate leaves and quite glabrous flowers. It is a native of Switzerland and Hungary, where it grows 2 ft. high, and flowers in April and September.

Section V.—The Silvery-leaved Daphnes.

14. *Daphne Tarton-raira* (The Silvery-leaved *Daphne*) *L.* [Synonym—*Passerina Tarton-raira*, *Schraeder*.]—The leaves of this elegant plant are small, obovate, nerved, alternate, silky, and persistent, with the branches weak, irregular, and scarcely ligneous; the flowers are axillary, solitary, somewhat globular, broadest towards the base and concentrated at the mouth, sessile, pale pink, silky externally, and with imbricated scales at their base; the leaves of this kind are remarkable for their smallness and silkiness, and the whole plant for its white silvery appearance. It is a native of France, grows 18 in. high, and flowers in May and June. Previous to the Linnaean arrangement *Tarton-raira* was the principal name by which this plant was known, and, according to Gerard, it originated

with the French from its rarity, for, he says:—"Tartou-raira, called in English Gutwort, which growth by the sea, is cathartical, not of any long continuance among us, and a stranger very goodly to behold, and therefore, in the mother-tongue of the Massilians, is called Tartou-raira." The Daphne Tartou-raira is quite hardy if planted in a dry, sheltered situation, and is best increased by seeds, which can easily be obtained from France, for it does not transplant well except when young.

15. Daphne tomentosa (The Tomentose Greek Daphne), *Lamarck*. [Synonyms—D. Tartou-raira major, *Hort.*; D. T. tomentosa, *Loudon*; D. villosa, *Linneus*; D. argentea, *Springer*; D. sericea, *Hort.*, not *Lamarck*.]—The leaves of this kind are oblong-obtuse and covered on both surfaces with a dense tomentum, which gives them quite a hoary appearance. The flowers are small, sessile, pale-straw coloured, with the tubes densely covered with white villous hairs, and come out in axillary clusters, imbricated with scales at their base. This kind is easily distinguished from the Tartou-raira of the French by its greater stature, small tubular-villose flowers,* and larger and more obtuse leaves, which are covered with tomentum instead of silky down. The Woolly Daphne is a native of Greece and Asia Minor, where it attains a height of from 2 ft. to 3 ft., and flowers from May to July. The Daphne Lutetiana of the Paris Gardens is a slender dwarf-growing plant of hybrid origin, somewhat resembling the Tartou-raira, which is its female parent. It is pretty, but difficult to cultivate, except in pots, and flowers in May and June.

Section VI.—The Flax-leaved or Alpine Daphnes.

16. Daphne alpina (The Wild or Mountain Mezereon), *Linneus*.—The leaves of the Mountain Daphne are linear-lanceolate, a little obtuse, alternate, small, deciduous, and tomentose beneath. The flowers are of a pale yellowish-white, tubular, silky outside, sessile, very fragrant, and produced in axillary, aggregate clusters of fives from the sides of the branches. The Mountain Mezereon is a low, branching, deciduous shrub, 2 ft. high, which flowers from April to June, and produces its round red berries in September. It is a native of Austria, Switzerland, France, and Italy, and was introduced in 1759.

17. Daphne altaica (The Altaian Daphne), *Pallas*.—The leaves of this kind are obovate-lanceolate or oblong, broadest towards the outer extremity, and narrowed downwards, glabrous on both surfaces, deciduous, somewhat glaucous, and yellowish-green, especially when young. The flowers are sessile, in terminal umbels of five, white and scentless, with the tubes of the flowers rather slender, and the lobes of the calyx broad and revolute. The Altaian Daphne forms a neat, compact, deciduous shrub, 3 ft. high, with slender shoots of a reddish-brown colour. It is a native of the Altai Mountains, in Siberia, flowering in May and June; introduced in 1795.

18. Daphne pubescens (The Downy sub-evergreen Daphne) *Linneus*. [Synonyms—D. Tartou-raira pubescens, *Loudon*; D. Thymelæa italica, *Micheli*.]—The leaves of this kind are linear-lanceolate, alternate, pointed, sub-evergreen, and somewhat thickly placed along the branchlets on old plants; the flowers are axillary, five or less in each axil, sessile, yellowish white, shorter than the leaves, and with the tube thread-shaped and downy. This is a fine sub-evergreen shrub, which grows 3 ft. high, with the stems simple and pubescent. It is found wild in France, Austria, and the States of Venice and Lombardy, producing its flowers in May and June among the leaves which partially hide them. It is nearly related to Daphne alpina, and was introduced in 1810.

19. Daphne Gnidium (The Spurge Flax or Mountain Widow Wyle) *Linneus*.—The leaves of the Spurge Flax are 1 in. long and 1½ lines broad, linear-lanceolate, acute-pointed, glabrous on both surfaces, persistent, and very similar in size and shape to those of the common Flax; the flowers are rather small but numerous, in terminal, panicle racemes, very fragrant, and of a pale yellowish-white slightly tinted with pink, and the tubes, which are rather short and stout, are thickly coated with a coarse white down. The D. Gnidium is an elegant little evergreen shrub, with numerous terminal panicles of sweet-scented, pinkish-white flowers, which in autumn are succeeded by small, globose, red berries. It is a native of Spain, France, Naples, Italy, and Greece, where it grows to a height of 2 ft., and flowers from June to August. This species retains the name Gnidium from the probability of its being the true Gnidium of the Greeks, who named it after Gnidus, a promontory and town in Asia Minor, where Venus had a temple dedicated to her; it also bears the vernacular names of Widow Wyle and Spurge Flax, and is said to be much used in the south of Europe for dyeing wool

a yellow colour. It is rather tender, and is chiefly propagated by grafting on the common Spurge Laurel, and thrives best when planted in a mixture of peat and old road sand.

20. Daphne Aucklandi (Lord Auckland's Daphne), *Lindley*. [Synonym—D. mucronata, *Royle*.]—The leaves of the Afghan Daphne are linear-lanceolate, acute-pointed, glabrous, glossy-green above, and persistent. The flowers are in terminal clusters, at first of a greenish-white, but eventually of a pale straw colour, and scentless; produced in April and May. This species forms a stiff evergreen bush, from 2 ft. to 4 ft. high; it is found in great abundance in Peshawar and on the snowy ranges of Kunawur and other parts of the Western Himalayas, at elevations from 10,000 ft. to 12,000 ft., near the limits of perpetual snow, constituting the chief vegetation. It is also found on the hills from Cabul to Jellahabad, and was first sent to England by Lord Auckland, when Governor-General of India, as "the shrub from the inner bark of which the Afghans prepared the matches for their match-locks." It is perfectly hardy, and bears a considerable resemblance to Daphne Gnidium, and produces an excellent yellow dye.

21. Daphne viridiflora (The Green-flowered Daphne), *Aiton*.—The leaves of the Green-flowered Daphne are obovate, entire, quite smooth on both surfaces, glossy green above, pale beneath, persistent, and about the size of those of Daphne collina; the flowers are rather small, tubular, smooth, bright glossy green, scentless, and in terminal heads, appearing in April and May. This species forms a thickly-clothed evergreen bush from 2 ft. to 4 ft. high, on the lower or outer mountains of Nepal, whence it was sent many years ago by Dr. Wallich to the Royal Gardens at Kew; but being tender, and one of the least desirable of the genus, on account of its flowers being green and scentless; it appears now to be lost in this country.

Section VII.—The Thymelæa Daphnes.

22. Daphne Thymelæa (the Milkwort-like Daphne), *Linneus*. [Synonyms—D. alpina glabra, *Plukenette*; D. glabra, *Noisette*; Passerina Thymelæa, *De Candolle*.]—The leaves are small, lanceolate, glabrous, crowded, persistent, and of a glaucous hue. The stems are much branched, with the branches simple and slender, and the branchlets warted; the flowers are small, pale yellow or straw coloured, axillary, sessile, and produced on the sides of the branches; the berries are small, and of a yellowish colour when ripe. This kind is a native of Spain and France, near Montpellier, where it forms a branched evergreen shrub, 3 ft. high, flowering from February to April. It is called the Wild Olive in Spain, and is tender, and requires protection in winter around London. Professor De Candolle and other Continental botanists consider that this kind to belong to the genus Passerina, or Sparrow-worts, but as it is found recorded in all English works as a species of Daphne, I have retained it as such in the present enumeration; it, however, is very distinct from all the other species, both in habit and general appearance.

Section VIII.—The Mezereon or Leafless-flowering Daphnes.

23. Daphne Mezereon (The common Mezereon), *Linneus*. [Synonym—D. Mezereon rubrum, *Loudon*.]—The leaves of the common Mezereon are rather large, lanceolate, or oblong-lanceolate, smooth, and deciduous; the flowers are thickly distributed over the leafless twigs of the past year, mostly in threes, but sometimes in twos or fours, and produced before the leaves develop in spring; they are agreeably fragrant, of a bright pink colour, and are produced in February and March. The berries are very acrid, and thickly set along the shoots, green at first, but bright red when ripe in September. The D. Mezereon is a well-known, deciduous, fastigate shrub, which grows from 3 ft. to 4 ft. high, and is much valued in gardens and shrubberies for the beauty and fragrance of its flowers in the early months of the year, when, as Cowper says, its branches are "though leafless, well attired and thick, beset with blushing wreaths investing every spray." The Daphne Mezereon is found in woody situations in the northern parts of Europe; in England it is rare, being only found in the southern and western parts. Baron Welden found it in Dalmatia. The whole shrub is poisonous to human beings, though the berries are a very favourite food with fuchs and other birds, more especially the robin. The bark and branches afford a yellow dye, and, when chewed, excite an unsupportable sensation of burning in the mouth and throat, and when applied to the skin in a fresh state or infused in vinegar raise blisters. The berries, also, which are even more acrid than the bark, have been known to produce fatal effects on children, who have been tempted by their beauty to eat them. The best remedies in such cases are oil, fresh butter, or some emollient, to allay the violence of the inflammation. The common D. Mezereon is increased by seeds, but if they be suffered to get dry before being sown they will remain two years in the soil

* The woodcut given in the "Arboretum Britannicum" as that of Tartou-raira, belongs to this kind, and shows the tubular flowers.

before making any progress; while, if sown in the autumn when ripe, and immediately after gathering, they will generally come up the following spring. The best time for transplanting the *D. Mezereum* is in October, as it begins to vegetate so early; and the most suitable soil for it, and one in which it thrives best, is a loamy soil, to which has been added a liberal supply of old road drift and rotten leaves.

There are the following varieties of the *Mezereum*:—*Daphne Mezereum* fol.-albo, *Loudon*. [Synonym—*D. Mezereum album*, *Hort.*]—This variety only differs from the ordinary form in having white flowers and yellow berries. *D. Mezereum* autumnale, (the Autumnal-flowering *Mezereum*), *Loudon*. [Synonym—*D. Mezereum sempervirens*, *French Garden.*]—The Autumnal-flowering *Daphne Mezereum* differs from the common form in not being fastigate in its habit of growth, but spreading, and in having larger leaves and deeper-coloured flowers, which first appear in November and continue in succession to the end of March. The leaves are also retained much longer on the plant, especially in mild seasons, but the berries are seldom or ever produced.

24. *Daphne Fortunei* (Fortune's Chinese *Daphne Mezereum*) *Lindley*. [Synonym—*D. Genkwa*, *Siebold.*]—The leaves of this beautiful plant are oblong-lanceolate or ovate-oblong, thin, alternate or opposite, deciduous, and, when fully matured, covered with soft fine hairs, but when young, quite silky; the branches are downy, slender, and more or less ascending; the flowers are rather more than 1 in. long, tubular, with the border divided into four rounded, oblong-obtuse, uneven lobes, of which the inner are the smallest, deep lavender or bluish-lilac covered externally with closely pressed hairs, and densely arranged in clusters of four along the last year's shoots in March and April before the leaves are developed. The *Daphne Fortunei* is a deciduous, slender, upright-growing shrub, and one of the earliest harbingers of spring; it seldom attains a height of more than 3 ft., but with numerous long, slender, downy twigs, which, like the *Mezereum*, are leafless in winter, but in spring thickly garnished with large, tubular, violet-coloured flowers, which spring from the axillary buds along the shoots before the leaves appear. Mr. Fortune found this kind at Ningpo, Shanghai, on the Ohusan Hills, and on many of the hills in the province of Che-kiang, but never in a wild state in the southern parts of the Chinese Empire. Dr. Siebold found it in Japan, and published an account of it in his "Flora of Japan" under the name of *Daphne Genkwa*, that being its vernacular in Japan, while the Chinese name for it is *Nu-lan-se*. Fortune also states that it is used medicinally by the Chinese in the same way as the *D. Mezereum* is in Europe; the bark, being extremely acrid and producing blisters on the skin, is much used by the Chinese doctors in cases of rheumatism. This beautiful shrub is easily increased, either by cuttings of the half-ripened wood or by grafting on the common *D. Mezereum*. It is perfectly hardy, and grows well in any good garden soil if kept moist during the growing season. Introduced in 1844. The *Daphne Championi* of Mr. Bentham, a kind not yet introduced, is an elegant, slender, deciduous shrub very similar in all respects to *Daphne Fortunei*, and was found on the Ohusan Hills. It, however, differs from that kind in being altogether more slim, and in having very much slenderer and smaller flowers, which are of a whitish colour.

25. *Daphne Houtteiana* (Van Houtte's Purple-leaved *Mezereum*) *Lindley*. [Synonym—*D. Mezereum* fol.-purpureis, *Hort.*; *D. M. fol.-atropurpureis*, *Hort.*; *D. M. atropurpureum*, *Hort.*; *D. Houttei*, *Louv.*; *D. Van Houttei*, *Hort.*]—The leaves of this kind are from 3 in. to 3½ in. long, and 1 in. broad in the widest part, oblong-lanceolate, somewhat pointed and tapering much towards the base, quite smooth, deciduous and deep green, stained with purple on the upper side when fully developed, but when quite young and in the bud state, of a dark purple colour. The shoots, when young, are also of a purple colour, but when old, light brown, stout, and spreading; the flowers are small, dark purple, quite smooth, and are produced along the shoots of the previous year, before the young leaves appear, on short, lateral, axillary, leafless projections, mostly in threes, but sometimes in twos or fours, with slender tubes and long lobes more or less reflected, and supported generally by a pair of long membranous bracts at the base of each cluster. This singular kind forms a robust spreading bush 3 ft. or 4 ft. high, with all the leaves collected on the young branches, while the old ones are naked. It is quite hardy, and flowers in the spring before the leaves appear, and is said to be a hybrid between the common *D. Mezereum* and *Spurge Laurel*, which originated in one of the Belgian nurseries. The following species of *Daphne* is not yet introduced, but deserves to be here noticed, so as to direct attention to its importation:—*Daphne papyracea* (The Indian-paper *Daphne*), *Wallich*. [Synonym—*D. cannabina*, *Wallich.*]—The *Bholia*, of the *Nepalaises*.]—The leaves of the Paper *Daphne* are from 2 in. to 2½ in. long, and ¾ in. broad in the widest part, oblong-elliptic, or oblong-lanceolate, rather distant,

alternate, smooth, persistent, and when young more or less glaucous on the upper surface; branches irregularly spreading, few and stout; flowers in terminal clusters, tubular, white, fragrant, and similar in size to those of *Daphne odora*. This species is found growing plentifully in the mountains of Bhotan and Nepal, at elevations of from 4000 ft. to 8000 ft., where it attains a height of 4 ft., and flowers from March to May. A soft kind of paper is made from the inner bark of this kind in Nepal and Bhotan, which possesses the advantage of being strong, not liable to crack, or be injured by insects in India.

The following kinds were formerly included among *Daphnes*, but are now separated, and form distinct genera, viz., *Daphne papyrifera*, *Siebold*. [Synonyms—*D. chinensis*, *Lamarck*; *D. Gardneri*, *Wallich*, the *Edgworthian chrysantha* of *Lindley*.] *Daphne tinifolia* (The Bonace Bark Tree of the West Indies), *Swarzewski*, is now *Nordmannia tinifolia* of Drs. Fischer and Meyer. The *Nordmannia cordata* of Loudon's "Hortus Britannicus" (1850) is a Boraginaceous perennial, and identical with the old *Borago orientalis* of Linnaeus, although in the "Hortus Britannicus" it is erroneously said to belong to the Natural Order Thymelacae.

A Custard Apple flowering in England.—The North American Custard Apple (*Asimina triloba*) is now in bloom here. Our foreman says he has known it for over fifty years, and this is the first time he has either seen it or heard of it producing flowers. In his dictionary Faxton calls it pale purple, and states that it flowers in August. Our plants seem to contradict this statement, as the flowers are reddish-brown, and before this month is out the plants will have finished flowering; the flower before it fully expands is green. Our plants are about 5 ft. high; we hope that they will ripen fruit, as we are anxious to see what it is like.—ROBERT OSBORN, *Fulham*. [A figure showing the curious leathery-looking flowers of this plant will be given in our columns shortly.]

Cultivated Brambles.—I am glad to find that you have figured and described the beautiful Bramble (*Rubus deliciosus*), which I consider well worth a place in every shrubby border and wild garden. *R. spectabilis* is another attractive plant, which has fresh green leaves and delicate rosy flowers; and its ally, *R. odoratus*, an old but very lovely species, with scented leaves, bears great rosy flowers, the petals of which are curiously crumpled. The double-flowered form of our common Blackberry is one of the best of all the species for margins of natural rocks on outlying portions of the pleasure grounds and semi-wild woodland walks. One of the most delicate of all the rosy-flowered species is *R. arcticus*, a dwarf kind, well suited for culture on rock-work. It is wild in N. Europe and America; and in Sweden its fruit is preserved in enormous quantities for winter consumption. To these may be added *R. biflorus*, the White-washed Bramble, a kind now common in our gardens; and one which is effective as a wall plant even in winter when trained among Ivy.—B.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Overcrowding of Trees in London Parks.—The way that very fine young trees are now crowded together in many parts of the London Parks, preventing their development into good or even middling specimens, is far from creditable. Along Rotten Row and Piccadilly, the jamming together is such as would not be tolerated in any other place where any attention was paid to trees. The trees are robbed of light and room above, and of food and moisture below.—V.

Copper Beeches at Clumber.—The fine old Copper Beeches in the pleasure grounds here are at this season grand objects amongst the many and different tints of green surrounding them, more particularly our Copper Beech avenue, with every second tree a Scarlet Florn in full blossom.—J. MURRAY, *Clumber*.

Embothrium coccineum in England.—This brilliant-flowering tree has already, we learn, attained a height of from 25 to 30 ft. in Cornwall. Even if it only grows there it will be a remarkable gain for our gardens. Mrs. W. Duffield has drawn it for THE GARDEN, and we hope to publish a fair portrait of the plant in due time.

Rhododendron Dalhousie in Cornwall.—We have here a plant of *R. Dalhousie* in full bloom in the open air; it has 140 flowers open, and is a magnificent object. It is grafted on *R. ponticum*, and has been planted out about ten years, and during that time has never lost its buds through frost—while we have several other plants about the place, seedlings on their own roots, that lose their buds in sharp winters, 8° of frost being sufficient to destroy them.—"Gardeners' Chronicle."

Rate of Growth of Forest Trees in New England.—Mr. J. W. Manning, of Reading, Mass., gives his experience in the "Boston Cultivator" of the growth of forest trees. Norway Spruce and Scotch Larch were planted, and in nine years the Spruce trees were 15 ft. high with 12 ft. spread of top. In fourteen years the Larch were 30 ft. high, with a spread of 20 ft., and a circumference of 4 ft. at the base. One Larch was 40 ft. high in seventeen years. Silver Maple trees planted in 1864 are now 35 ft. high, and 7 to 10 in. in diameter at the base. Elms planted in 1856 now range from 30 to 40 ft. high, and are 15 in. in diameter.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Vines without Fire-heat.—Where Vines are grown in plant houses and not excited into growth by more fire-heat than is required for keeping frost from the plants, they will be more than usually late this season, owing to the long continuance of cold unless weather which we have had. In some cases the crop will only now be large enough to thin, an operation which should be attended to at once; as should also that of stopping and regulating the shoots; inattention to the latter is frequently the cause of unfruitfulness, especially when the Vines are weak. Where too much wood is left, the strength of the Vines, instead of being concentrated in the formation of that which is required for the ensuing season's crop, is uselessly divided in sustaining a quantity of superabundant shoots that have afterwards to be cut away; if, to assist root-action, it is considered advisable to let more shoots remain than are necessary to carry the number of bunches the Vines are allowed to bear, more than one shoot to each spur should not be left, otherwise the evil alluded to must occur. Where Vines are in the late condition to which I have just alluded, it will be necessary at once to push them on as fast as the other occupants of the house will permit, by regularly closing the house sufficiently early in the afternoon to shut in a considerable amount of sun-heat; if this be not done, the fruit will neither have time to ripen nor the wood have a chance of getting sufficiently matured.

Climbers and Shade.—In houses devoted to the cultivation of decorative plants, grown either for their flowers or the beauty of their leaves, the effect is much improved by the use of climbing plants trained to the rafters in the usual manner; but, elegant as these unquestionably are, and much as they contribute to hide the objectionable straight lines of the wood or ironwork, the extent to which they are allowed to cover the roof must be very limited, unless there is a disposition to sacrifice the health and appearance of every plant occupying the body of the house that requires full light in which to grow. No greater mistake can be made than allowing roof climbers an unlimited amount of room in plant houses. Indeed, in the case of amateurs who may possess only a single house, and who keep this entirely devoted to the growth of flowering plants, with perhaps a few fine-leaved ones, it would recommend the matter to be well considered before any climbers are introduced at all; for even with the most spare growers that can be so employed those that occupy the body of the house will be injured to some extent. During the middle of the day, in bright weather, the climbers will possibly do little harm, and to plants in flower they may even be an advantage by breaking the force of the sun's rays; but for every hour they are of benefit to plants underneath them, there occur a dozen in which they do serious injury, and that in proportion to the extent to which they obstruct the light. If amateurs use them in houses of the description under consideration, they should employ only the most spare growers, such as will furnish but a moderate number of pendent shoots, avoiding all strong rampant-growing kinds, for although it is easy to keep the latter within bounds by a free use of the knife, yet this work does not always receive attention, or there is a reluctance to cut away the shoots. The more light the house affords from the principle upon which it is constructed, and the favourable position in which it stands, the more roof-climbers may be allowed. During bright sunny weather in the summer months, most flowering plants will last longer in bloom if they are shaded in the middle of the day, but nothing is more common than to see this so much overdone, that the whole are seriously injured by the obstruction of light through the material employed being too thick or the use of fixed shading. Where either of these evils exist it is impossible for the plants to remain long in a satisfactory state. It should always be borne in mind that, that almost every plant which we cultivate under glass receives in its native country considerably more light than our climate affords; therefore, wherever blinds are used they should in all cases be attached to rollers, so as to be easily drawn up and down as occasion requires, and they should never be allowed to remain down when the sun does not shine upon the house. Even in the case of Ferns (with the exception of the Filmy species and a few that exist naturally in shady situations), they thrive much better fully exposed to light when the sun is not upon them.

Fuchsias.—Plants of these that have been flowering for some time will be benefited by manure-water, but they must not have it applied too strong. All seed-pods should be removed as soon as the flowers fall off; when these are allowed to remain until they are fully matured the strength of the plants is taxed to a much greater extent than in the production of flowers. Such as are intended for late flowering should have their flowers picked off as soon as they are formed.

Lilies.—The earliest amongst these, such as *L. auratum* and *L. oximium*, will now be coming on fast, and should be assisted with manure-water. The soil must never be allowed to get dry, especially after it is filled with roots, or the bottom leaves are sure to become yellow and fall off, and when several bulbs are grown in a pot so as to exhaust the soil the lower leaves will suffer even if watering be well attended to unless stimulants are used. In the case of *L. auratum* the varieties differ greatly, both in habit and time of flowering; in a dozen bulbs, taken promiscuously as imported, there will generally be a difference of one-third in the height to which they will grow, and in the time of blooming of at least a couple of months, which, at once points to the necessity of growing them in separate pots. If there should be the slightest appearance of greenly upon them this should be at once removed, or it will destroy the leaves. They should be neatly tied to sticks thin but sufficiently strong to support them; for Lilies, Willows, are equally good, and look as well as painted deal. Turn the plants frequently, so as to prevent their being drawn to one side. Late flowering kinds, such as the different varieties of *L. lancifolium*, should be set in a thoroughly light open situation, where they will not become drawn. Syringing overhead two or three times a week will keep them clean, without which it is not possible for the foliage to remain green and healthy until the flowering is over. On this not only does the good appearance of the plants depend, but it has also much to do with the strength of the bulbs for another year, as the longer the leaves remain fresh the more strength will be stored up in them.

Petunias, especially the double kinds, of which there are now so many fine dwarf-growing varieties, make most useful pot plants, either for greenhouse decoration or for standing in room windows. Cuttings of these that were struck in the spring should now be moved into 6-in. or 7-in. pots, have their points pinched out, and be neatly tied to a few small sticks; they will succeed well in ordinary loam, to which a little leaf-mould and rotten manure should be added, and a sprinkling of sand: place them near the light so as to keep them dwarf and bushy, as on this their flowering capabilities will much depend.

Camellias that flowered about Christmas, and which after blooming were at once placed in heat, will by this time have matured their growth and formed flower-buds of a considerable size; the plants should not be allowed to remain too long in heat, or they may get too forward; but now is the time when their season of blooming may be regulated—and not afterwards by submitting them to heat as is often attempted—which almost invariably ends in the buds falling off before they expand. As soon as the largest buds acquire the size of Haws, the plants should be placed in a cool house shaded from the full sun, but, where there is plenty of air: they will not require so much water as during the growing season: on no account must the soil be allowed to get dry, or loss of buds will be the result.

Kitchen Garden.—Continue to plant out winter Broccoli, as the plants from the different sowings get large enough for the purpose; it is best to grow a moderate number from sowings made at different times, as by this means a continuous supply is much more likely to be kept up than it otherwise would be. Keep the hoe going during favourable weather, stirring the soil as deeply as the roots of the different crops will permit without interfering with them; do not use the rake amongst vegetable crops with a view, as is often done, of giving the ground a trim appearance—it is much better in the rougher state, as left by the hoe; under such conditions it does not lose moisture so fast in dry weather as it otherwise would, and, when showers fall, the water will penetrate the surface instead of running off, as it does when the ground is smooth.

Stoves.

A genial moist temperature must now be maintained by using the syringe freely among the plants after closing—keeping the pathways, the under parts of the stage, and any other available surface, well damped during the forenoon, or while the ventilators remain open. Fine-foliaged plants will now be the chief attraction in the above structures, and in order to promote a free growth they should be supplied with plenty of tepid water at the roots, shifting them on from time to time as they fill their pots and require more room.

Caladiums and others of that class do best in loose, rough soil, such as fibry loam and leaf-mould, or peat and the former, so that their roots can ramble freely and water pass readily through. To render these of use for conservatory or room decoration, they must be gradually inured to more air and a cooler temperature than what is necessary to grow them in, otherwise their leaves soon drop or curl, giving them a shabby appearance and spoiling their beauty for the

remainder of the season. Few plants are more effective for the embellishment of dinner-tables or similar purposes than dwarf, sturdy *Caladiums*; and, where plants are much in request for that kind of decoration during the summer months, a good selection should be kept in suitable-sized pots, available for service at any time. If subjected to plenty of light, their stems and leaves will become much stouter and stronger, with the colours brighter and more fully developed than when shade is employed beyond what is absolutely necessary to keep them from burning.

Marantas and Alocasias delight in shade and plenty of atmospheric moisture, which can be secured by placing them on inverted pots over tanks, that the bottoms of those in which they are growing may stand an inch or two clear of the water. In such positions they are very easy to cultivate, and rarely show any disfigurement round the edges of the leaves, as they sometimes do when there are sudden fluctuations in the amount of humidity immediately surrounding them. Young plants of *Alocasia metallics*, *A. Lowi*, and others of that type, must be kept well above the rim of the pot when shifting them into others of larger size, which operation should be performed at once if it be desired to grow them on as quickly as possible. Well drain by the use of plenty of crocks, and put in a mixture of rough, fibry peat and Sphagnum, packing it closely and securely round the collars of the plants, taking care not to injure the points of the large fleshy roots protruding through the old ball. When packing the fresh material about them, shake in a little silver sand, and place a few pieces of charcoal amongst the peat and Sphagnum to ensure its porosity; after which water freely during the remainder of the growing season. A *macrorrhiza* variegata requires different treatment as to soil and the way it is potted, for which purpose good fibry loam and peat, used in a rough state, is the most suitable. This, like the others, requires plenty of water while growing, and must therefore be well drained. The same conditions as to atmospheric moisture and shade necessary for the others will suit this perfectly. This variety has unfortunately a tendency to revert to the green form and lose its variegation, therefore, in making the requisite divisions for potting, only those showing the best marked leaves should be retained for growing on. Any that are already established and are now filling their pots with roots, should be assisted occasionally by giving them weak manure-water, which will add considerably to the size of the leaves and improve their appearance.

Sanchezia nobilis.—Where variegated plants are much in request for conservatory decoration during the summer months, no better or more striking plant can be had than *Sanchezia nobilis*, which is alike remarkable for the size of its leaves and the rich yellow bands of colour traversing each side of the principal veins. From the great substance of the foliage and the comparatively hardy nature of the plant over most other stove subjects, it stands well in the cool, dry air of a conservatory, and in positions where it would be quite unsafe to place *Crotons*, with many of which in point of leaf-markings the *Sanchezia* will compare most favourably. Cuttings put in now under hand-lights in any shady part of the stove, will soon root, and, if grown freely on during the summer, make fine useful plants for next season. To get the leaves of large size, they must be potted in good, fibry loam and leaf-soil, with sufficient sand to keep the whole porous and open, that water, of which they take liberal supplies when growing, may pass freely through. Any about to be removed for decorative purposes should first be placed in a cooler and more airy house than that in which they have been grown, so as to harden them gradually and prepare them for the change. In order to have their leaves in the best possible condition, they should be frequently sponged, to remove dust or other deposit that may have gathered on them from the impurity of water used in syringing.

Crotons.—Plenty of light, heat, and moisture, are the conditions most favourable to the growth of these, and to secure which the plants should be placed well up to the glass and kept freely syringed both morning and afternoon, shutting up early so as to close in the sun-heat, by which means fires may now, in most cases, be entirely dispensed with. With the rapid progress these are now making liberal supplies of water at the roots will likewise be necessary, especially to those that are confined in small pots, and to such weak liquid manure will be of great benefit. Any just struck, and others more advanced, that it may be desirable to grow on faster than the general stock, and to which colour for the present is of no consequence, may be subjected to more shade, which, if accompanied with an increase of heat and atmospheric moisture, will have the desired effect. *Crotons* are well adapted for table decoration, especially the long narrow-leaved varieties, such as *C. Weismanni*, *C. spirale*, *C. interruptum*, and others of that class grown with single stems and confined to 6-in. pots, which sizes are generally as large as can be

accommodated on the limited space of a dining-table. Plants from 18 in. to 24 in. high are mostly preferred for this purpose, and to get these furnished with healthy, full-sized leaves down to the pot, the leading points of strong shoots should be taken off and struck under close hand-lights or large bell-glasses, which they will soon do if plunged in brisk bottom-heat. As soon as they attain the requisite height nip out the leading shoots close to the axil of the top leaf and carefully disbud any that start up the stem the moment they show themselves, by which means the whole strength of the plant is forced into the leaves, causing them to attain an unusual state of development, as well as enabling the grower to keep the plants in the same serviceable state for a great length of time. In order to develop their rich colours to the fullest extent the plants should be placed where they can have plenty of light and be well syringed to keep down red spider, which, if allowed to attack them ever so slightly would cause such a disfigurement as to render them unfit for the purpose required.

Draenas.—These most accommodating plants may at once be made use of for decorating conservatories or other cool structures, provided they have been prepared for a week or two, by being gradually hardened in a drier and more airy house than that in which they have been growing. There are few, if any stove subjects that will endure the sudden changes of temperature, or anything like the amount of hard usage that *Draenas* will, and now that we have so many of noble aspect affording such a wide range of colour in their leaf-markings, no establishment, where ornamental-foliaged plants are in request, either for summer or winter decorations, should be without a good stock of the best and most distinct kinds. Where they are required for special purposes, such as placing in vases in halls, rooms, &c., and have consequently to be confined to small pots, plenty of water must be supplied at the roots, otherwise the tips of the leaves will die off, thus giving the plants a shabby appearance. Any that are now in rooms or other positions where dust is likely to settle on them, should have their leaves carefully sponged occasionally, which will add much to the brightness and beauty of the plants, and help to preserve them in health. Small growing stock must be well attended to, and shifted on as they require more pot room, keeping them in a close moist atmosphere to push them on as fast as possible. In order to get as much colour in the leaves as the different varieties are capable of attaining, those likely to be required for table decoration should be placed where they can obtain plenty of light, without which the beautiful markings characteristic of them are not fully brought out.

Anthuriums are now making their young leaves, and as much of next season's success in blooming depends on the growth the plants make at the present time, no pains should be spared in giving them the necessary attention. Moderate shade, a close, moist heat, and plenty of water at the roots are the conditions necessary for success in growing this perhaps most useful of all stove-flowering plants. See that the old leaves do not overlap the young ones now emerging, and come crippled and deformed, as every fully developed leaf the plant can be made to produce adds to its strength and capacity for blooming. Sponge carefully the foliage that is sufficiently mature to be handled in that way, so as to remove any scale or deposit, and keep them in a clean, healthy state.

Celosias and Cockscombs.—Young-growing plants of these should be potted in rich soil, and plunged in slight bottom-heat in pits or frames, where they can be kept well up to the glass, to prevent them from becoming drawn. Shut up early and syringe freely, so as to keep down red spider, as when the leaves of either of these become affected by this pest the beauty of the plants soon disappear.—*J. SHEPPARD, Woolverstone Park.*

Orchids.

Many *Dendrobiums* are now in full growth; they should therefore be placed in a warm, moist, airy house, and be kept well supplied with water until the pseudo-bulbs are fully developed. Most of them are true epiphytes, having a pendulous habit, and in making their new growth the middle leaves are arranged so as to throw off any water that may by chance fall on them; even the young growth of those varieties whose pseudo-bulbs when mature assume a more erect habit exhibit this tendency. As the young growths of most *Orchids* are tender and impatient of water, it is bad practice to tie them in an upright position, thereby depriving them of the benefit of their natural habit of growth, and running the risk of losing the heart, in which case the plant would have to start new growth, probably too late to come to maturity; if the plants are doing well and making sturdy growth they will need little or no support until the pseudo-bulbs have filled out, when, if tall-growing varieties, they may be trained into the required forms; if they are making fragile growth it shows that they are either in too warm or too close a place,

and such plants should have the young growths looped up to prevent them from breaking, and should be placed in a more airy part of the house as near to the glass as possible. The *Masdevallias*, which should be in the cool *Odontoglossum*-house, must be liberally supplied with water, and any of the plants which have not *Sphagnum Moss* growing on the tops of the pots should have some of the old material removed, and its place supplied by filay peat and living *Sphagnum*, it being important that the Moss should be in a growing state; air should be freely admitted day and night. Look carefully after insect-pests in all the houses, clean the plants, alter their relative positions, and rearrange them.—JAMES O'BRIEN.

Kitchen Garden.

Various opinions are held as to the utility of earthing-up vegetable crops, and if "doctors differ, who shall decide?" As regards myself I have not the least doubt that the practice is beneficial to certain crops and injurious to others. I would therefore advise that each use his own judgment in the matter, and earth-up or not, as may be thought best. These remarks are suggested through the effect of the wind upon our Brussels Sprouts, and which, though planted in shallow trenches and filled in to the general ground level as they grow, now require to be either staked or earthed-up, and for obvious reasons we prefer the latter course. Some kinds of Potatoes also require earthing-up, others will succeed without it, notably the short-topped kinds, but the taller-growing sorts require a good ridge of soil to support the haulms; rain is just as effective, if not more so, when it descends to the roots between the ridges. In favourable weather keep the hoe at work amongst all growing crops; such labour is never lost, but acts beneficially in two ways—first, by assisting the growth of the crops; and, secondly, by preventing the growth of weeds. If all seedlings, such as Onions, Carrots, Parsnips, &c., have not yet been finally thinned out, they must be attended to at once, or serious injury will accrue to the permanent crops, and though such work is more expeditiously and better accomplished in showery weather, if there should be no rain water should be applied artificially, and the task completed forthwith. Proceed with the planting of the various kinds of winter greens as the ground becomes vacant—Colesworts and Savoys are especially acceptable in autumn and early winter, and should therefore be planted in quantity; another sowing of the former should now be made, and these will produce a supply for use in the depth of winter. If the weather continue dry Cauliflowers will require liberal watering, and each alternate watering should be with diluted sewage, or manure-water of some kind; Lettuce, also, if desired large and crisp, should have plenty of water; Celery, too, as soon as the plants are well established, will be all the better for it, though if mulched at planting time none yet will be required. Plant out the later batches of Celery, in doing which any side-shoots or suckers should be taken off, but however long the plants may be, do not cut off the tops when the plants have become drawn: such a practice is to be thoroughly condemned. If Peas were sown in shallow trenches, as recommended some weeks ago, they may now be filled up to the ground level and staked, at the same time mulching them either with stable litter or short grass. A sowing should now be made of both early and late kinds; the best early is William I., and the best late sorts are Veitch's Perfection, British Queen, and Ne Plus Ultra. As soon as Peas are plentiful, cease cutting Asparagus, for to continue cutting it much longer will prove disastrous to next year's supply. Clear the beds or plantations of weeds, and then give a dressing of salt or guano, or irrigate with sewage; as this vegetable is a gross feeder, and quite fails to thrive satisfactorily on anything like poor land. Remove the flower or seed stems from Seakale, Rhubarb, Sorrel, and Horse Radish; such operations may seem of but trifling import, but their removal conduces to the strength of the plants in the way most desirable. The weaker stems of Globe Artichokes should also be thinned out; the finer produce of those left will more than compensate for the smaller number of heads; indeed, if we could but apply this rule (*viz.*, thinning) to every kind of crop, we should have better and finer produce, and not at such irregular intervals as sometimes occurs. Keep up the desired supply of Spinach by sowing a small quantity fortnightly. Top Broad Beans, and sow once more if there be a demand for them. Stake and pinch out the points of Runner Beans, and sow a good breadth of Dwarf French Beans—the best kind yet introduced is Canadian Wonder. Vegetable Marrows, Ridge Cucumbers, Tomatoes, and Chillies should have unremitting attention in assisting and forwarding growth, for our longest growing season is far too short for their well-being.—W. WILDSMITH, *Hockfield*.

Temple Gardens.—The gardens of the Inner Temple are, by permission of the Benchers, thrown open to the public between the hours of six and eight every evening.

THE FRUIT GARDEN.

APPLE NOMENCLATURE.

THE efforts made to rectify the nomenclature of Apples by Downing and others have been truly valuable, and yet the subject is but in its infancy. I shall, in my references to works upon fruit-growing, rely mainly upon Mr. Downing's large work of 1870. I do this because no other author has seemed to have the courage to grapple with this subject to the extent that he has done. As an insight into what we have to do in the direction of a correct nomenclature, I find that twenty-nine varieties of Apples have as many as 370 names, averaging thirteen to each. I also present another embarrassing feature as regards correct nomenclature, *viz.*, the almost countless number of times the word "Pippin" is used as being descriptive of distinct varieties. I find this meaningless word, when applied to the Apple, used no fewer than 124 times in the work already referred to, as descriptive and distinctive of different varieties, and in eighty-three instances used as a synonym of other varieties; altogether it is used 207 times as a distinctive name. Well might the President of the Pomological Congress, at the meeting at Philadelphia, in 1869, express a hope that the word Pippin might be dropped from our catalogue. The words Bellefleur, Pearmain, Romanite, and Spitzenberg, with some others of like import, are calculated to and do frequently mislead persons seeking to grow fruit. Bellefleur means beautiful flower, and the Yellow Bellefleur, which is presumed to be the type of all the Apples bearing this name, when in full bloom, is a sight most beautiful to look upon. Its blossoms are very large and white, presenting an object of special attraction, and yet in most instances a large proportion of these flowers are abortive. The other Bellefleurs are so named more from their resemblance in shape to the Yellow kind than to their bloom—the very point where the name originated; hence the name is embarrassing and confusing. Pearmain, as used to designate a particular variety of the Apple, is not satisfactory, and tends to confuse the nomenclature. Pearmain must mean either Pear-shaped or Pear-flavoured. This point has never, to our knowledge, been settled. Most Apples bearing this name are either round or conical, with the large end at the stem, while most Pears have the small end at the stem. The terms Romanite and Spitzenberg are equally bewildering as a distinctive name when applied to the Apple. True, many of these terms, perhaps all of them, are preceded by an adjective, thus converting these terms into family or classified names. But even in this view of the case they fail as signally as when used to designate special varieties. A correct nomenclature, I contend, should proceed upon the principle of making the name expressive of something belonging to the specimen—either the place of its origin or the originator, the time of ripening, the size, shape, colour, or quality of the fruit. Some two or three of these should be grouped together in such way as to make the name express as much of these characteristics as can conveniently be thrown together without making the name cumbersome. There is still one other phase of this subject that is more confusing than any other, and that is, the using the original name and synonym interchangeably; sometimes using the original for the synonym, and at other times using the synonym for the true name. A few examples of the incautious use of these terms will show how very embarrassing the practice is to even those who are well acquainted with fruits. Let us take the *Early Harvest*. Here the *Tart Bough* is given as a synonym, or as the same Apple under another name. Then the *Tart Bough* should not be described as a distinct variety: and yet it is so described. The *Tart Bough* is also given as a synonym of *Summer Pippin*. If then the *Tart Bough* be the same as *Early Harvest* and also as *Summer Pippin*, then the *Early Harvest*, *Tart Bough*, and *Summer Pippin* are but the same Apple, the *Early Harvest*; yet we have them described as three distinct Apples. We have the *Early Harvest* and the *Summer Pippin*, and they are quite distinct in size and colour and time of ripening. How confusing this to one who is seeking to procure certain varieties to plant an orchard! The *Buckingham*, again, is a leading Apple in the south and west, but is sought after and procured under a multiplicity of names.

Having been taken from Buckingham County, in Virginia, to North Carolina, and there having received the name of Buckingham, from the county from which it was taken, it has become through the south and west pretty well established by this name; yet Queen is the original name by which it was known in Virginia during the latter part of the last century. In the extreme south it is known by the name of Equinettee as the original name, and Buckingham and Kentucky Queen as synonyms, together with various other local names. Fall Queen is one of the synonyms by which it was known in Kentucky for many years, and if Fall Queen and Buckingham be the same, as is admitted by the books, then the Fall Queen cannot be properly used as synonym, or as the original for any other variety; and yet there is an Apple described as originating in or near St. Louis some years ago, bearing the name of Fall Queen. It has for its synonyms, Gros Pommier, Haas, Hoss, and Horse. Now if the Fall Queen be the same as Buckingham, then Gros Pommier, Haas, Hoss, and Horse are the same. But the Fall Queen or Buckingham is known to have originated in Virginia, and the Fall Queen, as described in "Downing's Selected Fruits," is known to have originated in St. Louis County, Mo. If these two Fall Queens could possibly be the same Apple, then the Gros Pommier, the Haas, the Hoss, the Horse, and the Buckingham would all be the same. The true Fall Queen is a large red Apple, ripening in November and December, while the Horse is a large yellow Apple, ripening in August—as different from the Queen as two Apples can well be. Any one ordering the Horse Apple supposing he would get the Fall Queen would be quite disappointed. This also goes to show how important it is not to use original names and synonyms interchangeably. The Golden Sweet is given as the original name of a fine summer sweet Apple, ripening in the west in July; Orange Sweet is given as the synonym, and yet the one ripens in July and the other in September on the same ground; Northern Sweet is given as an original name, and Golden Sweet as a synonym; Munson Sweet is given as an original name and Orange Sweet as a synonym. Hence Golden Sweet, Orange Sweet, Munson Sweet, and Northern Sweet, must be one and the same Apple, if the synonym and the original be the same. There would then be the very same Apple ripening the one in July, one in September, one in September and October, and the other from October to February. By their synonyms all are made to be the same Apple, while they are described as four separate and distinct varieties. This is enough to confuse the most watchful of us all. Further the Ortlely, a fine old Apple, has for some of its synonyms, the White Pippin, Greasy Pippin, Warren Pippin, and Vandyne. Now if these be really synonyms, they are each nothing more or less than the Ortlely itself under different names. But each of these synonyms, excepting the Greasy Pippin, is described as an original and distinct variety. The Greasy Pippin being a synonym of Lowell makes Lowell and Ortlely the same. They are, however, quite distinct, the one ripening on the same ground in September, the other keeping all the winter; the one having a close, the other an open core. Whenever we shall have left off describing synonyms as original names, we shall have made a long stride towards having a much purer nomenclature than we now have. I will give but one other case of this confounding of original names, and using them interchangeably with synonyms, viz., that of the Primate. The Tart Bough was given as a synonym of Early Harvest, and is also given as a synonym of Primate, a fruit so distinct in tree and fruit as to cause surprise at being called the same. The Powers is also given as a synonym of Primate; the one is supposed to have originated in New Jersey, the other in Ohio; the one an old variety, while the other is comparatively new. The Primate ripens in August, the Powers in October. Here then we have the Early Harvest ripening in July, the Primate ripening in August, and the Powers ripening in October and November, described as one and the same Apple, and also as distinct varieties. This is making confusion doubly confounded. We think no one can but see the great impropriety of thus confounding the use of originals and synonyms. Let us now direct attention to a few names of Apples which really mean anything or nothing, as one chooses to make them; such, for instance, as Early Ripen. There are hundreds of Apples that

will answer this description, hence it is no guide to the recognizing of any one in distinction from another. Fourth of July is another of those meaningless names; the fourth of July comes at the same time whether the Apple is ripe or not; hence both of these Apples should have a prefix or an affix to make the name intelligible.

There is another phase of this evil in nomenclature which we wish to present, and that is, that some of the State and local societies assume the right to give new names to old varieties whose names, to them, are not known. I have only space to notice a few cases. The first is that of our own State Society calling a fine winter Apple the Kansas Keeper, when it was known to be some old variety, but the kind not recognised. This Apple was obtained from the Ham Bros.' Nursery, and of course were grafted trees, consequently could not have originated in Kansas, in 1855. The next case is that of the Eastern Iowa Society. This Society has named an Apple the Iowa Blush, the trees of which are known to have been obtained from Dayton, Ohio, more than twenty years ago, under the name of Sweet Bellefeur. While it is evident that the trees did not produce fruit true to name, it is equally true that the trees did not originate in Iowa. The name Iowa Blush leads to the declaration that the trees were raised from seed in Iowa. This is shown to be delusive. This Iowa Blush will no doubt turn out to be some known variety. The next case of this kind we find in Virginia, where the celebrated Newtown Pippin is called Albemarle Pippin.

Let us now point out what we believe would be a remedy for such evils. Let the National Society appoint a committee, whose duty it shall be to revise and fix upon the proper nomenclature of our leading Apples, and report their findings to the next session of the Society for adoption or amendment. When this is done, let the Society cause a circular to be sent to all the State societies, requesting them to conform their several catalogues to the National in regard to its nomenclature; requesting also that the State societies make the same request of the county and local societies to do the same, and for these last to urge upon nurserymen to make the same conformity; and in this way I think the work will be done. This system once fairly inaugurated will, I think, have a most desirable result, which will be to have a uniform catalogue of the original names, with the proper synonyms attached thereto. Whenever each nurseryman shall conform his catalogue to the National catalogue having the original names at the top of his description in capitals, with the proper synonyms in italics, immediately below the proper name, there can be no difficulty in knowing at a glance whether or not he has the variety called for. Under an arrangement of this sort, fruit-growing will become a general business in those portions of country adapted to it, in consequence, mainly, of a universal confidence growing out of this general intelligence produced by a uniform nomenclature.—J. H. HOWSELY, in the American Pomological Society's Proceedings.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Blister on Peach Leaves.—This is doubtless caused by the piercing east winds which we have been experiencing; the flow of sap gets checked and put out of its usual channel. Some leaves, therefore, have more than their share of it, and functional derangement is the result.—H. M.

Hard Rusty Strawberries.—(see p. 639) Hard rusty fruits often occur on the later forced plants, and are caused by exposure to bright sunshine and a high temperature. If plants be shaded from the fierce rays of the sun, or if they be turned away from the sun so that the pot shades the fruit, and the house sprinkled on hot days to keep the air cool, rust will not be troublesome. Early fruit is seldom affected by it.—J. S. W.]

Ants Injurious to Peaches and Nectarines.—We have a south wall against which are planted several Peach and Nectarine trees, and for the last three or four years they have been infested with ants in vast numbers; the leaves curl, discolour, and fall, and the fruit is small and ripens imperfectly. Many so-called remedies have been tried, but unsuccessfully. Can any of your correspondents who may have experienced similar trouble aid us by naming a cure?—WILKINSON.

Rust on Grapes.—I consider that rust is caused nine times out of ten through carelessness when thinning. Young men, when employed in thinning Grapes, are apt to touch one bunch with the hand while working at another, and every berry with which the hand comes in contact is sure to rust. Rust arises from other causes, such as steam from hot-water pipes; but hair-rubbing I have proved will produce it. I do not think it occurs when Grapes are in bloom, but when the berries are swelling.—USA.

THE INDOOR GARDEN.

GREAT ROSY-FLOWERED ODONTOGLOSSUM.

(*ODONTOGLOSSUM VEXILLARIUM*.)

At the last exhibition of the Royal Horticultural Society, Mr. Richards, gardener to Baron Rothschild, at Gunnersbury, sent two of the finest examples of this species ever seen in English gardens—or, it might be added, in Europe—and to which a gold medal was awarded. These specimens bore thirty-six and forty-two flowers respectively; of the largest plant we made the accompanying sketch, which will give some idea of its floriferous character when skillfully grown. The fresh, vigorous condition of these plants—foliage as well as flowers—was in every way remarkable. It may be worthy of mention that case after case of this species, and also of *O. Warszewiczii*, have been sent to this country with their contents either dead or dying. These fine plants from Gunnersbury therefore prove that though a plant may travel badly, yet it may not be difficult to cultivate when once obtained in a living state. The plant, of which the annexed is a representation, bore very delicate whitish flowers, softly suffused with rose, while an even more robust plant of the large deep-rosy-flowered variety bore four spikes, on which there were in all thirty-six flowers, and all these were the produce of one pseudobulb. An importation of this plant in good condition has just been made by Mr. W. Bull, a fortunate circumstance, considering it is so handsome and so amenable to cultivation. B.

BIGNONIAS.

THE various species of these plants that require a higher temperature than that of an ordinary greenhouse, are mostly strong-growing evergreen climbers, suitable for decorating the roofs of large stoves or warm conservatories. They belong to a somewhat numerous family, but only a limited number can be recommended for general cultivation, many being of such a rampant habit as to render them unfit for growing with other plants through the tendency they have to outgrow and over-shade those that are near them. Most of the species usually cultivated should not be planted in a house where a very high temperature is kept up, as the heat and necessarily accompanying moisture render them unmanageable under such conditions, inducing growth to an extent that precludes a disposition to bloom freely. The flowers are produced in panicles, generally during the summer season. They are very effective, especially when the plants are allowed a moderate amount of freedom, not keeping them too closely tied in, but letting them hang in a wavy, natural manner. One point should be especially observed in their cultivation, as also in other subjects of a similar free habit, that whatever cutting-in becomes necessary during the growing season to keep them in bounds, should be performed with judgment and with due regard to their flowering; this will be best effected by a total removal of such portion of the shoots as is found to be necessary, but not a general shortening of the whole. Where this is done the effect generally will be to stop blooming altogether, or to

limit the extension of growth in such a way as to prevent the production of anything above a meagre display of flowers. So far as practicable, it is better to prune after the blooming season is over, as then the flowering shoots are not so much interfered with.

Bignonias may be propagated in different ways—by root-cuttings, layering the shoots, or by cuttings made of young shoots. When they are increased by layers, shoots should be selected that have sprung from near the collar of a plant, operating at a time when the wood is fairly matured. Procure some 6-in. pots, which drain and fill with three parts peat to one of sand, pressing it down firmly into the pots; place these on the surface of the border in which the plant is growing, bring the shoots down to the pots, make a slit in the wood at the under side of the shoots, the knife entering just at the lower side of a joint, and passing upwards longitudinally through it for about an inch. A tongue-shaped piece is thus formed, composed of about half the substance of the shoot, which should be bent down and secured by small hooked sticks in the pot where the incision has been made, covering it about an inch deep in the soil, which must be kept

watered. In this position it should remain until well rooted, after which it can be severed immediately below the point where rooted. When root-cuttings are used, pieces about the thickness of a quill should be taken off existing plants early in the spring, before growth has commenced, and cut into bits about an inch in length, inserting them singly in thumb pots in a mixture of two-thirds peat to one of sand, with half an inch of sand on the surface, leaving the thickest ends of the cuttings just a little above the sand, placing them in a temperature of 65° or 70° during the night, and a few degrees higher during the day. In a few weeks shoots will be formed from near the

Specimen of *Odontoglossum vexillarium* grown at Gunnersbury.

tops of the cuttings, which will also soon begin to make fibrous roots. Treat them afterwards as with plants grown from cuttings made from the shoots, giving them larger pots as required. When these plants are increased by cuttings made from the young wood in the spring, shoots should be chosen that are not too hard, or, in the opposite extreme, too soft and watery. The former will be slow in rooting and difficult to make grow freely; the latter will most likely damp off. Select those that are moderate in strength, and if they can be taken off with a heel at their junction with the old wood, they will be much more likely to succeed. Pot them singly in small pots in sand, confine under a propagating glass in a brisk heat, give moisture and shade when rooted. Gradually inure them to the full air of the house. After they have fairly commenced to grow, give them pots 3 in. larger. They will grow in either loam or peat, but during the first stages peat has some advantages. Use it now broken moderately fine, adding one-sixth part of sand. Place them in a light situation in a house where the night temperature is kept about 70°, and 10° higher during the day with sun-heat. Shade slightly in very bright weather, giving sufficient air to keep the growth from being drawn up weakly. By the end of July the plants will most likely have filled their pots with roots,

and should be at once shifted into others 3 in. larger, at this time mixing half loam with the peat. Pot them moderately firm, and place two or three sticks in the pots, to which the shoots should be trained; it is better not to stop them, as in most cases a single shoot for a considerable height will be the most suitable form for the plants to assume. Keep them regularly trained round the sticks, not letting the shoots twine round these, or they will most likely suffer when they have to be removed. As the autumn advances give more air, discontinue shading, and reduce the temperature; but never allow them to be too dry at the roots, as, in common with other evergreen subjects, their leaves will be injured if the roots be over-dry. Winter them in a temperature of 55° or 60°. About the beginning of March they should be planted out where they are intended to remain, as they are naturally too large for pot culture, unless the pots were much larger than would be either slightly or convenient, their nature not being such as will admit of partial shaking out and removal of the soil annually, as with plants of a deciduous nature.

The border in which they are to be grown should be well drained, as the plants when they get large will require copious waterings; 6 in. of broken bricks should be placed in the bottom, allowing a sufficient egress for the water. Over the drainage put some fibrous material to prevent it getting clogged with the soil, which should consist of good loam with a little rotten-manure added, and enough sand to keep it open. This should be 12 in. or 15 in. in depth. When the plants are turned out, the roots ought to be carefully loosened from the ball and spread out, covering them about 3 in. or 4 in., pressing the soil moderately firm. The shoots should then be trained in the places they are to occupy. As the roots begin to grow freely give water when required, and as soon as the shoots have attained the height where they are desired to branch out, the points should be pinched to cause them to break, repeating the operation at intervals as they grow, until a sufficient number exist; these should be regularly trained to wires fixed for the purpose; for, if neglected (especially in their younger stages), they will twine round each other, becoming an entangled mass that will require cutting back to get the plants into shape. During the growing season they will be much benefited by a free use of the syringe every afternoon. After the allotted space is covered the plants should be cut in each season when the flowering is over, after which they will commence to make growth for the ensuing season's blooming. As the soil becomes exhausted each spring, before the roots begin to move, an inch or two should be removed from the border, replacing it with new material; and through the growing season manure-water will be a great assistance.

The following species are deserving of cultivation:—*B. Chamberlayni*, a strong-growing yellow-flowered plant, from Brazil; *B. olnata*, a desirable variety, moderate in growth; *B. venusta*, an autumn-flowering, orange-coloured kind, from South America; *B. argyrea violascens*, a handsome species; and *B. littoralis*, a free-growing, handsome kind from Mexico, producing purple and red flowers.

*Bignonia*s are not so subject to insects as some plants. *Aphides* will sometimes make their appearance on the young growth, but can be destroyed by fumigation. Where the syringe is freely used during the growing season, red spider will be kept down. If they become affected with scale, it must be removed by sponging, by which means and a free use of the syringe they can also be cleansed from mealy bug.

T. BAINES.

VENTILATION OF ORCHID-HOUSES.

PROPER and evenly-distributed appliances for the ingress of pure air and the egress of that which has become vitiated are essential to the healthy development of all plants cultivated under glass, but to none more than Orchids, which from their nature cannot thrive long without good ventilation. Without this they will languish and die, even in the best of houses and under the best cultural skill. Two cases fully corroborating this assertion came under my notice last year. In both instances complaint was made that the plants had not flowered nor grown satisfactorily for a considerable time, and that they had remained year after year in much the same condition in which they then were. On looking hastily round all seemed right; the heating was good—perhaps excessive; but, on closer inspection in one case, not the slightest means of ventilation was to be found, save the doors at each end of the house. In the other there were no bottom ventilators, and but few top ones, and these were said to be seldom opened. I ventured to say that want of ventilation was the chief cause of the plants doing so badly, and that they would have grown much better had they been placed in an ordinary well-ventilated greenhouse. Pure air Orchids must have, and if they cannot get that they will not succeed; excessive heat without plenty of air acts on them in much the same way as excessive cold does; it stunts them and prevents their flowering. When, therefore, any particular degree of heat is given as that proper for an Orchid-house, it should not be understood that the temperature recommended is all that is necessary; on the contrary, when the thermometer has reached that point, or a little above it, air must be admitted, and if the day be not sunny or likely to be a warm one, the heating apparatus should be kept going sufficiently to insure the maintenance of the required heat after the ventilators have been opened.

The principles on which proper ventilation depends are simple: as the air in a house becomes heated it ascends to the highest point and there ventilators should be placed to permit it to escape; the colder and heavier air from the outside should be admitted by means of ventilators placed in the brickwork of the house below the level of the pipes and near the foundation; bottom ventilation is of little use without top ventilation, and *vice versa*; but, by carefully regulating the two together, a healthy atmosphere may be maintained without causing draught. Air should always be given in a careful and systematic manner—not by opening a few of the ventilators wide and leaving others closed, on the contrary, on the temperature of the house attaining the required point, the ventilators should only be opened an inch or so, after which, if it be a house containing growing plants, the floors should be damped, and in an hour or so as much more ventilation should be given as the temperature inside and the atmosphere outside will permit, taking off the last portion given as early in the afternoon as can well be done, and finally shutting up according to the season of the year or the state of the weather. In foggy weather, which is fatal to Orchid winds and very injurious to the plants themselves, or when keen east winds prevail, it is best to regulate the temperature by means of the heating apparatus, and on no account to open the ventilators; at other times, during the dull season, when the outer air is favourable, a little should be admitted in the middle of the day; and in spring, summer, and early in autumn every available means should be resorted to for the proper admission of pure air, as well as for the maintenance of the necessary heat, for on these matters the health of Orchids mainly depends. Many methods of ventilating have been from time to time invented, but, though based on correct principles, they have in some cases been found too intricate to work well. The old-fashioned sliding light, with cord, pulley, and weight for giving top air, is also objectionable, inasmuch as it entails an unnecessary amount of wear and tear to the structure; the cord and weights in the house are also unsightly, and the cord itself liable at any time to break, and allow the lights to run down, an occurrence which, happening at night or during inclement weather, would be productive of much injury to the plants. The means of giving side-ventilation by swinging sashes level with the stages is unsuitable for Orchids, for when the ventilators are open the cold air comes directly in on the plants, causing a draught in certain parts of the house and in the lower part, while underneath the stage the air remains unchanged. This mode of ventilation is a favourite one with hot-house builders. I have seen it applied to many Orchid-houses, but in building new houses the cultivator should in all cases be consulted in reference to ventilation, the arrangement of the staging, and other matters of detail. The best and simplest way of ventilating Orchid-houses of all temperatures is to have a glazed ventilator about 2 ft. in width swinging on pivots at each end of the house at the highest point; the portion of the ventilator below the pivots should be square and that above corresponding in shape to the highest point of the end of the house, so that when air is given half may swing outwards; square ventilators of a similar size opening

Climbing *Petræa* (*Petræa volubilis*).—This old-fashioned plant is not so much grown as it ought to be; it is one of the most graceful and distinct of stove climbers, bearing long pendent racemes of lilac-purple flowers, and dark green *Clerodendron* or *Combretum*-like leaves. Perhaps, like many other useful plants, such as *Embothrium coccineum*, *Spiræa* (*Exochorda*) *grandiflora*, *Ipomæa Horsfallii*, *Clematis montana*, and *C. (Astragene) austriaca*, the difficulties of propagation have restricted its distribution. In the "Botanical Magazine" (t. 628) it is described as a native of Martinique, where it scrambles up trees to a height of 15 ft. to 20 ft. It is as distinct in its way as *Bougainvillea glabra*, and would soon become popular were it more generally kept in stock in our nurseries.—B.

outwards on hinges should be arranged alternately (if the house be a span roof one) at a distance of about 5 ft. or 6 ft. apart; on either side of the roof at the highest point during fine weather all the ventilators may be opened alike, but in bad weather that side should not be opened on which the cold wind blows. These ventilators if within reach should each be fitted with a flat piece of iron about an inch in width and 2 ft. in length, having holes in it at regular intervals apart into which a pin fixed into the bottom bar of the framework of the aperture fits, thus keeping the ventilator open the required distance. When arranged in this manner the movable part, when open, forms a covering over the aperture, which consequently need not be closed even during rainy weather; if out of reach such ventilators should be fitted with an iron rod fixed to a ring, in the end of which a cord, running over a pulley fixed in a similar position to the pin previously mentioned, should be fastened; by pulling the cord the ventilator is opened, and by making it fast, it is kept in the required position. The shading should be so arranged as to interfere as little as possible with the egress of the hot air. The bottom ventilators for the admission of air in houses built on a level with the ground should be just below the level of the pipes; they should be placed at distances apart of say from 4 ft. (for cool houses) to 6 ft. right round the house; each opening should be 18 in. in length and 6 in. in width (or smaller if placed at less distances apart), and they should be fitted with a grooved and slightly projecting framework, so as to allow of a cover of wood or slate running along it, and closing the aperture, after the manner of a sliding box-lid. These ventilators should be covered on the inside with coarse gauze or perforated zinc, which will check the too rapid entry of the air, and serve to keep out troublesome insects. When the ventilation of a house is arranged in this manner, and carefully regulated, the top ventilators allow the over-heated and vitiated air to escape freely, and the bottom ones admit a proportionate quantity of the pure air.

It is highly essential that air be admitted below the level of the pipes, and near the floor of the house, and to do this some difficulty is experienced in the case of sunk houses; the best plan is that in use at Broomfield; it is effected by digging holes down to the foundation on the outside of the house, at regular distances apart, openings being made in the brickwork at the bottoms of the holes, and the holes themselves bricked up a few inches above the level of the ground, so as to form small air-shafts about 18 in. in length and 6 in. in width. The opening into the house is covered with coarsely perforated zinc, and for the regulation of the air the shafts are covered with lids on the tops, which are opened as required. These lids are of wood or slate, and are quite free, not running in grooves, and consequently not quite air-tight, but the little air which passes through them when shut is beneficial rather than otherwise in a properly heated house. The chief care required by these air-shafts is to see that they do not get choked up with leaves and rubbish. Even in sunk houses, with solid earth left on which to set the plants, this kind of bottom ventilation might still be effected by laying a drain-pipe from each opening in the brickwork at the bottom of each shaft under the place on which the plants stand, the outlet being a little above the pathway. For bottom ventilation of very large houses, or those built in blocks several together, where it is difficult to get sufficient openings in connection with the outer air, a good plan is to lay a row of large drain-pipes along each side of the house immediately under the hot-water pipes, and another row up the middle beneath the walk if necessary; each row of drain-pipes should have the ends opening into the outer air, and should there be fitted with suitable covering to regulate or shut off the air as may be required; on the inner side they should have openings at regular distances apart along the house, the openings varying in size, the largest being in the middle, and each opening as it nears the end should become smaller, until the ends are close to where the air is admitted are but one-third the size of the middle one. In this way the middle of the house, where the greater facility for admission is offered, is well supplied with air, whereas if all the openings were of one size, the ends would be draughty and the middle imperfectly supplied with air. This is a good system, especially if care be taken to keep the pipes free from obstructions. These modes of ventilation may be applied to any Orchid-houses not at present properly ventilated, but in building new ones, of course, the ventilation should be carried out as the work proceeds. One other matter particularly affects the uniform distribution of air throughout a house, and that is, if the side stages be not of open work, an opening of about 2 in. should be left between them and the wall, to permit a portion of the air to circulate among the plants; in that way, the ventilators being placed below the hot water pipes, the air will have to pass over them before it reaches the plants—a point of considerable importance.

JAMES O'BRIEN.

Forcing Liliun longiflorum.—This lovely Lily is, according to "The Gardeners' Magazine," the best of the whole race for

forcing, and the most valuable when its forced flowers have been secured. It has many a time delighted us to see how easily we could secure an early and a vigorous bloom by putting some established plants in the Geranium-house soon after the turn of the year, and keeping them very near the glass with abundance of air. The flowers acquire a splendid development, and the plants are rarely troubled with fly or any other enemy. Plenty of light, plenty of air, plenty of water, with a little of something in it, and in due time there you are. As to the date of flowering, that will depend upon the temperature, and, as a matter of course, the temperature of a Geranium-house is quite high enough for any kind of Liliun, for these plants will not stand very much boiling or roasting. There is a cry for white flowers at Easter, and people who can obtain Callas are delighted, but everybody who is interested in decorations at that season would sooner have Lilies than ought else.

A GRACEFUL TABLE PLANT.

(SONCHUS ELEGANTISSIMUS).

This plant, which was lately exhibited by Messrs. E. G. Henderson, at one of the Regent's Park exhibitions, is remarkable for its soft, green, finely-cut foliage, and extremely graceful habit of growth. As a table plant it is peculiarly interesting, the leaves appearing semi-transparent under artificial light. It is easily cultivated in any warm

Sonchus elegantissimus.

plant-house or pit, in a compost consisting of turfy loam and leaf-mould in nearly equal proportions, with the addition of a little coarse sandstone grit to keep the whole porous. Several other varieties of Sonchus form very graceful decorative plants, and deserve a place in most gardens where slender-growing foliage plants are desired for dinner table decoration or small vases in the drawing-room or front hall.

B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Masdevalla Estrada.—Can any of your contributors learned in this class of plants inform me what is the difference, if any, between this variety and *M. lonocharis*, now to be seen in flower at Messrs. Veitch's, at Chelsea? Certainly a prettier gem in its way would be difficult to find; and, though not so showy as many of the tribe, its neat and very free-flowering habit render it desirable in all collections.—V.

A Gigantic Cactus.—Dr. Ernst describes, in the June number of the "Journal of Botany," a plant of *Cereus Swartzii*, the trunk of which he calculated measured 56 ft. in height. At 3 ft. from the ground it had a diameter of 18 in., and at about 30 ft. from the ground it divided into fourteen large branches.

The Fuchsia as a Basket Plant.—Perhaps the most suitable form of all for the Fuchsia is that of a basket plant. Walk under a tall Fuchsia, and it is impossible not to feel that the way to see Fuchsias to the best effect is to look up to them. The shoots, hanging over sides of baskets, or trained over their bottoms, are in the best position to be seen. The Fuchsia does also well in a basket. The slender habit of so many of the finer varieties admirably adapt them for such purposes. Plants for baskets require early and persistent stopping, to form dense dwarf bushes. The bottom shoots may also at times need to be tied over the sides. With a dense pendent habit established at first, there is little difficulty afterwards.—F.

THE KITCHEN GARDEN.

FRENCH ASPARAGUS BUNCHING.

EARLY in March last (see p. 254) we figured and described Mr. Conover's Asparagus buncher, and in contrast with it the very primitive form still in use by many Asparagus growers. The "Revue Horticole" about the same time gave engravings of four different bunchers in use in different parts of France; these we reproduce, not only because it is interesting to learn

Fig. 1.—Old French Buncher.

how gardening operations are performed in other countries, but because these different devices may afford some useful hints to those who may desire to make something of the kind for their own use. In France large areas are devoted to the field culture of Asparagus, and there are also immense esta-

Fig. 2.—Normand Buncher.

blishments for forcing it under glass; these two sources are supplemented by that put up in cans, of which large quantities are preserved for home use and for exportation. From one or another of these those who can afford it can enjoy Asparagus all the year round. The number of these bunchers

Fig. 3.—Sartrouville Buncher (empty).

at home and abroad show that the necessity for putting up Asparagus in neat bunches is generally recognized; if any one doubts that careful bunching pays, let him send to market loose shoots, or even bunches carelessly put up, with uneven ends and butts, and he will be fully convinced that when he has raised the crop he has accomplished only one step towards turning it into money. In regard to the size of the bunches,

that differs with the season; the length is 8 in. or 9 in., and the diameter through the centre from 4 in. for early Asparagus, to 5 in. for that which comes in later. In the French markets where articles are often purchased in small quantities, the large bunches are divided to make half and quarter bunches, and the marketmen have bunchers for doing this. Fig. 1 shows the oldest of the French bunchers; it consists of two pairs of wooden scissors with curved blades; to each short arm of one of these is fixed a wooden rod, which passes through a hole in the corresponding arm of the other, allowing the two to be placed at the desired distance apart; the scissor-like ends may be opened or closed, and held at the proper point by a string tied across the rods. The apparatus at fig. 2 is called the "Normand Buncher," and is in very common use. It consists of two boards each with a U-shaped opening; the rear one has a thin piece across it to keep the ends of the shoots even, and near the bottom four square rods, upon which the front piece slides; a part of the front piece has a

Fig. 4.—Sartrouville Buncher (filled).

thin board over it to add strength. In figs. 3 and 4 are shown the "Sartrouville Buncher," both empty and filled; its construction is shown so clearly that explanation is not needed; none of the parts are movable, the peculiarity about this is the back board, so contrived as to bring the tips of the shoots close together; when the frame is nearly full, the shoots are passed in through the wedge-shaped opening above. Figs. 5 and 6 show closed and open a more complicated affair; it is the form sold by the implement dealers in France, and

Fig. 5.—Argenteuil Buncher (closed).

known as the "Argenteuil Buncher." The board E slides in grooves in the frame D, D, and carries the two pieces B and C; the end A is like that in the preceding, arranged to draw down the bunch. The cross-piece F is merely for strength, and the circles near E indicate that underneath are cavities for the ends of the fingers, to facilitate the pulling out of the board. From among these Asparagus bunchers, and those previously figured, our readers should be able to fix upon one which will do the work neatly, and what is also important where there is a large crop, quickly. To have the Asparagus appear in the market in the best possible manner, there are several precautions to be observed. It is customary for the cutter to lay the shoots in handfuls along the rows; these should not be allowed to remain long, as they will curl and wilt; in handling keep the heads all one way. As soon as possible after cutting, wash, assort, and bunch; at least two sizes should be made, and the bunches should be of even

quality all through. Take pains to have the heads very even, and cut the butts neatly and square. Tie the bunches very tightly, or they will become loose in transport. The fault with all the French bunchers is that they have no means of pressing the shoots, a difficulty overcome in Mr. Conover's buncher, which allows the bunch to be held under strong

Fig. 6.—Argenteuil Buncher (open).

pressure until the ties are put on. Use flat ties; strong bast is generally used, and probably Cuba bast would be better than the native or Russia; fig. 4 shows the usual method of tying in France where Willow twigs are employed. When made up the bunches should always stand upright; if laid down they will become crooked. If obliged to keep the Asparagus for a day or two before sending it to market, place the bunches in a tub, in an inch or so of water, and protect them from light; keep them in a cellar.—“American Agriculturist.”

Advantage of Deep Surface-stirrings.—Heavy land works most unkindly—to use a local term—and unless the surface be freely stirred in a season like the present, crops can hardly be expected to progress satisfactorily. Owing to the heavy rains which we have had, the surface, where not well loosened up, is almost impervious, and by-and-by will crack into deep fissures, and let out every particle of moisture. The obvious remedy in the case of such conditions is to stir the surface freely when dry with a light steel fork. The hoe, although a most useful implement, will hardly do such work well this year, especially among Potatoes, or any other crop that may require earthing-up. And all such crops as Peas and Cauliflowers should be mulched early.—E. HOBDAY, *Ramsay Abbey.*

A METHOD OF FORCING ASPARAGUS.

The method of forcing Asparagus introduced by M. Jacquisson, of Chalons, a well-known horticulturist, is so simple that the annexed figure is almost sufficient to explain the matter. It consists of an ordinary wine bottle with the bottom cut off. These bottomless

bottles when well corked are placed over the Asparagus head just as it is beginning to rise above the ground. The Asparagus being thus protected not only grows fast but is so tender that the whole of it may be eaten. The air being kept from it, the development of the woody fibre of the plant is retarded, while that of the cellular tissue is accelerated. Cultivated in this way Asparagus is as expeditiously cut as when grown in the ordinary manner, sufficient light

passing through the bottle to show when the heads are ready for gathering. In addition to this the small amount of light which passes through the bottle gives the Asparagus a rosy tinge which greatly improves its appearance. At page 515 of the present volume of THE GARDEN, directions have been given for cutting off the bottoms of bottles, or bottomless bottles, the refuse of glass works, are not difficult to obtain.

COTTAGERS' LEEKS.

LEEKs, as stated by Mr. Groom (see p. 520), are not popular in East Anglia. I have many times recommended their culture, and offered plants of them to cottagers, but without any good result. In many other parts of the country, however, Leeks are held in high estimation, and there can be no doubt that they are both wholesome and nutritious. In the North of England and throughout Scotland they are much valued, and however small the cottager's garden may be, room may generally be found in it for a bed of Leeks. Leek shows in some places are not uncommon, and the productions in this way sometimes exhibited are marvellously fine. Notwithstanding this, however, Potatoes are almost the only vegetable which finds favour with cottagers, and these are planted year after year upon the same ground until it becomes Potato sick, and produces inferior crops; even in cases in which a change of seed is occasionally had recourse to on account of the numbers of small tubers which are almost unavoidably left in the ground, the stock soon becomes mixed and deteriorated, as more than one variety can seldom be satisfactorily cooked together. Unless a cottage garden be larger than such gardens usually are, late Potatoes might be excluded from it altogether, and to admit of this being done, a practice, which is not unusual in some parts of the country, might become general, viz., that of farmers allowing cottagers to plant a row or two of Potatoes in their fields on condition that they well manure the ground. This concession on the part of the farmer is not wholly a loss, and the advantage to the cottager is considerable, inasmuch as it leaves his garden at liberty for the culture of other crops, and enables him to adopt some system of rotation. But to return to the Leek; it enjoys, as Mr. Groom has truly said, almost an immunity from disease, as well as from the attacks of insects and vermin of all kinds, for should a hare or two pay a nocturnal visit to a cottage garden (not by any means an unusual occurrence), when morning dawns the cottager may find just enough of his Cabbage or Cauliflower plantation remaining to point out the place where it formerly existed; but the Leek bed he will always find to have been respected. The Leek will flourish in any kind of soil, but the richer or the more highly manured this may be, the finer will be the produce. P. GRIEVE.

Culford Hall.

IRRIGATION OF KITCHEN GARDENS.

LET us first advert to sewage irrigation in the neighbourhood of towns. This question possesses a double interest, the rendering of towns more healthy; and the utilization of the manure, which ought to be employed for increasing the fertility of the soil. Ever since 1867 experiments have been made with sewage in the plain of Gennevilliers (Seine), and the results have been most satisfactory. The large sewer of Paris, into which the several small ones run, forms, as it were, a subterranean stream, which flows into the Seine near the bridge of Asnières. This clears Paris to some extent of its sewage; but the result is not wholly satisfactory, inasmuch as the muddy torrent has considerably increased since Paris has been better supplied with water. Muddy deposits formed in the Seine at the mouth of the new tributary, and it was evident that the river was becoming infected. Engineers employed by the committee for sanitary improvements at first thought of purifying the water, and by mixing the solid matter with some chemical preparation, forming a valuable manure, but on being tried this method proved tedious and expensive, consequently they adopted the more simple and economical one of turning the sewage into the fields, where it soon gave proofs of its efficacy. The plain of Gennevilliers, joined to a part of that of Asnières, presented an area of more than two hectares, the soil of which was of a flinty character, and not very fertile. Nature had, however, as it were, placed it by the side of the sewer, so that it might be benefited by the rich manure which its waters contained.

In order that it might be properly watered, it was necessary to raise the torrent 12 metres; to pass it to the opposite side of the Seine, and give it an artificial fall so as to enable it to circulate all round the land; a steam pump was employed for forcing up the water, and on the bridges of Clichy and St. Ouen were placed cast iron pipes, which served for conduits; small channels in brickwork conveyed the water to the different parts of the land where it was required, and small sluices placed here and there enabled the cultivator to direct its current wherever he wished by simply digging out side trenches. Thus controlled the irrigation produced excellent results, especially in the case of vegetables—Cabbages, Artichokes, Asparagus, Cauliflowers, Turnips, Carrots, Beetroots, Cardoons, bulbous Chervils, Tomatoes, Melons, and Strawberries. All these, cultivated alternately, speedily acquired an enormous size, and were first-rate in quality. Plants, too, used for perfumery, and others, succeed admirably.

Rosos and trees—particularly fruit trees—grew in a most satisfactory manner, and the value of the ground has been increased from 90 francs to 550 francs per hectare. Light soil filters the sewage and clarifies it to such an extent that its water returns to the Seine in a clear state. There can be no doubt as to the good quality of vegetables grown by means of sewage; but it should, if possible, be applied underground not on the surface, as in that case it soils the plants. When applied underground, too, the air is kept free from disagreeable odours. In the case of permanent pastures the soil in time becomes sewage-sick, owing to the accumulation of detritus on the surface, but experience proves that there is no danger of this happening in land used for gardening purposes, the soil of which is being constantly dug up. The Agricultural Society of France intends to offer a prize in 1878 to the cultivator who has endeavoured to utilise sewage in the best manner and to the greatest extent.—"Revue Horticole."

WAYS OF DESTROYING THE COMMON THISTLE.

PRACTICAL MAN.—What may you be doing this morning? **THEORIST.**—Getting rid of these horrid Thistles. **P. M.**—You will not get rid of them if you go to work in that way. **T.**—Why not? **P. M.**—Because you attack them when they are only just appearing above the ground. **T.**—That is just the reason why I am attacking them. What ought I to do? **P. M.**—Wait till the autumn, and then draw them. **T.**—What! Let them grow up and gather strength? **P. M.**—Certainly. For every one that you cut off now three will come up in its place. **T.**—But what is the use of waiting so long before you begin to destroy them? **P. M.**—Why, you see, they can be got out their whole length in the fall of the year, and the rain runs into the holes left when they are drawn, and what remains rots away. **T.**—That is certainly a better way of destroying them, and will save me a world of trouble; it will be such a blessing to be rid of them for ever. **P. M.**—Oh! if you expect that, I fear you will be disappointed. **T.**—Why, did you not say that the wet would get into the holes after the Thistles were drawn, and destroy what remains in the ground? **P. M.**—But they will come up again for all that. Here **Theorist** was puzzled. He was aware that leaves are the lungs of a plant, and he was led to infer that vegetables were like animals in one respect, that they could not exist when deprived of these organs. Wishing to be well rid of the Thistles, and being told that drawing them was the only sure method of dealing with them, and that even after that operation they would appear again in the following year, he determined to go on with his experiment. The result was as follows:—He persevered through the first season, cutting them off as fast as they appeared, never allowing them fully to develop their leaves. There were, of course, none to draw at the fall of the year, and in the year that followed there were not so many to begin with; as the season advanced the call for the hoe was less frequent, and long before the winter set in not a Thistle was to be seen. It was rather late in the third year when **Theorist** took his hoe to commence an attack upon his enemy the Thistle, but after a most careful search he at last succeeded in finding—**ONE.**

Late Broccoli.—For several years I have tried the latest Broccoli I could procure, but only in a few cases have I been successful in gaining a decided advantage over the kinds with which we have been long familiar. Often, too, have I tried kinds under different names which have proved identical, not only in appearance, but also in time of coming into use, and except the seed comes to us in sealed packets, it can seldom be depended upon. **Veitch's Autumn Giant Cauliflower** and **Snow's Winter White Broccoli** are both valuable sorts, but we never get them true to name, except in packets sealed with the seed-grower's name. It is not uncommon for cultivators to save a little good Broccoli seed, and by choosing the latest

and finest heads from the stock for that purpose, a great improvement may be made on the original kind. At **Westwood Park Broccoli** of unusually good quality saved in this way is at present (June 12) in use, and likely to be until late in the month. The heads are fit for table before they are uncovered by the leaves, and, if left long enough, they grow to an immense size, and are very white.—**M. TEMPLE, Inpney.**

Dandelions as Salad.—The eloquent plea for the beauty of the Dandelion, in **THE GARDEN** of last week, reminds me also of its usefulness; in the early spring there are fewer sweeter salads than the young shoots of this plant. Some years ago I knew a French nurse who went out into Hyde Park with her charge, salad-basket in hand, as was her custom in the country. The police, spying her digging and storing, remonstrated, and finally apprehended her. They could speak no French, and she no English; and the basket and its contents were seized as proofs of her petty larceny. It was not till a lady, attracted by the crowd, recognised the nurse and her charge, that she was liberated. The contents of the basket were **Dandelions** and **Celandines**, quite enough for the salad of a good-sized family. By using them thus the numbers of a troublesome weed would be most lessened, while a sufficiency would doubtless be left to line the brook-side and embroider the meadow with gold.—**D. T. FISH.**

Stanstead Park Cabbage Lettuce.—Of all the Lettuces which I grow this is the best for winter and early spring. It is very hardy, and forms good hearts, and by using protectors it can be had all the winter, until the Black-seeded Brown Cos (a favourite in this neighbourhood) come into use early in the spring. The protectors which we use here are of our own construction, and are well adapted for the purposes to which they are applied. They can be made by any carpenter, and are neat in appearance. They consist of inch deal boards, the back boards being 11 in. and the front boards 9 in. deep. These are fastened together by cross pieces, and are grooved near the upper edge in order to secure the loose squares of glass which slide in from the ends, and form a roof. The frames are about a foot wide, and we find 6 ft. lengths most convenient for moving from one place to another. Such frames are most useful for protecting Lettuces, Peas, Radishes, and early Potatoes.—**DAVID LUMSDEN, Blochomb Gardens, Sleaford.**

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Early Peas.—I sowed **Ringleader** and **Dickson's First** and **Best** on the 2nd of February; my first gathering was picked from **Ringleader** to-day (the 9th), I shall gather from **Dickson's First** and **Best** on the 12th. One season I gathered **Ringleader** on May 22. These varieties are quite twelve days later this year than usual. We are now digging up a fall supply of **New Potatoes** from the open ground, the varieties are **Veitch's Improved Early Ashleaf** and **Mona's Pride**.—**RICHARD NISBET, Asarby Park Gardens, Lincolnshire.**

We are growing here **Ringleader**, **William I.**, **Little Gem**, **Racehorse**, and **Laxton's Shah**. From the last-named kind we gathered a dish this day (June 10); **Ringleader** will be from four to six days longer, but comes next. Everybody admits that **Mr. Laxton** is the raiser of two of the best late Peas, consisting of **Omega** and **Commoisier**, and this season proves that he is also the raiser of the earliest.—**R. GILBERT, Burghley.**

Early Paris Market Cabbage Lettuce.—We are now (June 9) cutting beautiful fire-hearted Lettuces of this variety. Its seeds were sown in boxes under glass early in March, and transplanted in April. In point of earliness and good quality, this is the best of the **Tom Thumb** section I have yet grown.—**E. HODNAX, Ramsey Abbey.**

Wheeler's Tom Thumb Lettuce.—We are just now, and have been for some time, using this excellent little Lettuce, the flavour of which is all that could be wished. I would strongly recommend it to all lovers of good and early salads.—**R. GILBERT, Burghley.**

Germination of Vegetable Seeds.—At the beginning of this year it was predicted that, in consequence of last season's bad harvest, seeds would have a lower vitality than usual, and that there might consequently be some difficulty in securing a good plant. Although our soils is difficult one with which to deal, I have never known seeds of all kinds to grow more freely or with more vigour than they have done this season. This I attribute in some manner to our constant practice of covering them with a compost made of charred and decomposed rubbish that daily accumulates from different sources, and which, when properly managed, forms a most valuable fertiliser.—**E. HODNAX, Ramsey Abbey.**

The Virtues of Celery.—Somebody has discovered extraordinary virtues in Celery. A writer, who is familiar with its virtues, says: "I have known many men, and women too, who from various causes have become so much affected by nervousness that when they stretched out their hands they shook like Aspen leaves on a windy day, and by a moderate daily use of the blanched footstalks of Celery as a salad, they became as strong and steady as other people." A number of other extravagant statements of the same kind are also given.

Trophy Tomato.—We have tried several of the newest and most highly praised Tomatoes extant without changing our conviction that the **Trophy** is yet the best. The **Arlington** is firm, solid, and of good shape, ripens with the **Trophy** or a little earlier. The **Conquerors** and **Victors**—both excellent early sorts—ripened the one with the other. A very few ripe Tomatoes were gathered upon the **Victors** first, but there was no difference in the average ripening. **Hathaway's Excelsior** is a beautiful variety of medium size, round, and solid.

NEW PLANTS, &c.

Dieffenbachia (late maculata) var. illustris.—A distinct and prettily-marked variety, having dark green leaves marbled irregularly with light apple-green and silvery-grey, the grey blotches being striped or dotted with narrow dark green markings.—"L'Illustration Horticole," pl. 234.

Eranthemum roseum.—An erect-growing stove shrub, having heart-shaped leaves of a rich, dark green colour above, and of a dull purplish-crimson tint beneath, and bearing erect, terminal spikes of dull, reddish-purple flowers. It forms an attractive foliage plant when young, but is not adapted for forming large specimens.—"L'Illustration Horticole," pl. 235.

Dahlia gracilis.—This is a Mexican plant discovered in the summer of 1873 by M. Roezli, and by whom it has been introduced to Continental gardens. It is of slender habit, having elegantly pinnate foliage, the leaflets being coarsely serrate. The eight-rayed flowers are of the brightest orange-scarlet colour, the disc being yellow. It appears to be nothing more than a slender-habited variety of the old Dahlia coccinea, which has recently been redistributed in English gardens by Mr. H. Cannoll. It is, nevertheless, a most graceful and effective plant, and one well worth a place in the herbaceous or shrubby border, and its brilliant flowers are well adapted for cutting.—"Gartenflora," t. 861.

Quisqualis sinensis.—A plant nearly allied to the Combretaceæ; it was introduced to English gardens long ago, and is figured in the "Botanical Register," xvii., t. 15. It is a native of China and the East Indies, and is of slender habit, having opposite oblong leaves and terminal clusters of long-tubed, purple-petaled flowers. It is interesting, but is not likely to be of service as a decorative plant.—"Gartenflora," t. 862.

Monopylia racemosa.—This is a large-flowered Gesneriad from South America, bearing terminal spikes of white, rosy-spotted Gesneria-like flowers. In general habit the plant reminds one of the continental pale-flowered Nögeliæ. The plant was raised from New Grandian seeds sent to Messrs. Veitch and Sons, with whom the plant has flowered, and, when more plentiful, it promises to be a useful decorative plant.—"Botanical Magazine," t. 6233.

Cotyledon teretifolia.—A distinct yellow-flowered South African plant, having long cylindrical leaves, the apices of which are pointed like arrow-heads. The flowers are borne in clusters at the apex of slender cylindrical stems, a foot high. It is a desirable addition to effective succulent plants, and well deserves culture.—"Botanical Magazine," t. 6235.

Does Phylloxera attack other Fruits or Plants besides the Vine?—Referring to the question raised by Mr. Ross (see p. 639), regarding the attacks of the Phylloxera upon the Vine only, I may state that all the experiments tried here failed to show that it would devastate any other plant except the Vine. Plums and other fruit trees were planted in the Phylloxera-infested soil, and still they continue to grow without any symptoms of being attacked. Clean, healthy Vines were, however, attacked and devoured immediately they were planted in the affected border. A striking instance, however, has come to my knowledge of the way in which the Phylloxera may be imported with other plants besides the Vine. A quantity of Roses arrived at a garden in Scotland from France in winter, when the ground was hard frozen, a bench-full of soil had been prepared for potting a quantity of young Vines, and in this soil the Roses were "heeled in." In due course the Vines were potted in the soil, and were immediately afterwards attacked by the insect, which could have been introduced in no other way than by means of the Rose trees. I do not think that there need be much alarm as to Phylloxera on our Vineries in this country, if it be vigorously attacked whenever it makes its appearance.—D. THOMSON, Drumlanrig.

Thinning Grapes.—Reference has been made in your columns (p. 484) to Mr. Douglas's mode of thinning Grapes, which I think might be imitated by any one who wishes to have handsome bunches, either for the dessert-table or for competition. Few will admit that bunches with the berries literally jammed together are either models for exhibition or for ornamenting dessert dishes; but, on the other hand, berries—however fine they may be in size and colour—which hang so loose as to show the foot-stalks and rub the bloom off each other, are discredit to the cultivator. On dessert dishes such fruit appears to great disadvantage. I have seen Grapes on many dinner-tables, and where they were compact without being jammed against each

other their appearance was very superior to that of loose bunches. I have been at Loxford Hall on two occasions, and specially noted the fine form of the bunches of Grapes and evenness of the berries grown there, showing that they had been skilfully thinned.—M. TEMPLE, Impney.

Rust on Strawberries.—In most cases the cause of rust on Strawberries may be traced to damp or cold chills when the fruit is in bloom; when it occurs upon out-door Strawberries, this is undoubtedly the cause of it. Syringing Strawberries in pots overhead ought to be discontinued at least a week before they come into bloom, and not renewed until the decayed petals have fallen off. If kept damp they adhere to the embryo berries, and frequently generate a fungus, which is injurious to the development of the fruit. Of all our hardy fruits the Strawberry is the most tender, and most liable to be injured when in flower. Imperfect fertilization may be the cause of your correspondent's hard and rusty Strawberries. He does not say whether the fruit was fully developed or not, but I think its failure may be traced to one or other of the causes just named. When I was in the habit of growing Strawberries in pots, my first lot often contained imperfectly developed fruit, an occurrence which I always attributed to imperfect fertilization.—J. THOMSON, Shawdon.

June Budding of the Peach.—This mode of getting Peach trees ready for planting in one season is, according to "Coleman's Rural," a matter of some importance. As soon as the shoots from which the buds are to be taken have grown about a foot, pinch the top so as to develop the buds. When the young trees to be budded have attained the thickness of a goose-quill, they may be operated upon. Bud about 6 in. from the ground, and in about ten days, if the bud looks fresh, it will have taken; loosen the bandage and pinch the top off the tree. In a short time the bud below will be sufficiently established to admit of heading back the tree to within an inch or two of the bud. Let the inserted bud start a few days, and then rub all others off.

Bandage Propagation.—The practice of slipping a branch and binding Moss or other material over and about the wound is an old custom. Six months or more ago we applied it to Pelargoniums with excellent results. In raising Tricolors from seed it hardly ever occurs that the whole plant is variegated. Here is a shoot perfectly green, here is one with leaves half variegated, half plain; still another shoot may be variegated with more or less uniformity—the only one upon the seedling, and it is this upon which we have to rely for establishing a "fixed" Tricolor of seedling origin. Those who have propagated cuttings in the usual way know that in spite of the most careful efforts the Tricolors sometimes fail to strike. In this case we should lose our variegated shoot and, perhaps, a year or more of time might be spent in its production. It was upon such shoots that we ("Moore's Rural") tried cutting the stem from half to three-quarters through—pressing the cut slightly open so that the parts should not grow together and then binding with Moss—sometimes placing a small quantity of damp soil as if it were putty underneath and covering all with netting, gauze, or merely tying with a tape or yarn. This of course must be kept constantly moist. In about the usual time required to strike the same cuttings in sand the roots will be found growing through the Moss, when the shoot may be cut off just beneath the bandage and, with or without removing it, placed in small pots. By this method we have never once failed, and, indeed, we believe it to be unfailing, even though attempted when, under unfavourable conditions of moisture and temperature, the sand-bed would prove useless. One advantage of this mode of propagation is that it may be accomplished during the winter in a conservatory or sunny window without marring the symmetry of the plant operated upon until the shoot is ready to be taken off. The variegated leaves hold their colours firmly while the callus and roots are forming, and the bandage may generally be concealed by the foliage. It is well to support the shoot which has been cut nearly through by a neat stick or prop, since incautious handling is liable to break it off. In this way many new and costly plants which one is desirous of increasing, and which one is timid about running any risk, may be treated with little fear of failure.

Taking Impressions of Plants in Colour.—M. Bertot, of the Paris Academy, has just made known a simple method of taking impressions of plants, requiring only a large sheet of paper, some Olive (or other) oil, black-lead, ashes, and resin (or copalony). The paper is first lightly oiled on one side, then folded in four, so that the oil may filter through the pores, and the plant may not come into direct contact with the liquid. The plant is placed between the leaves of the second folding, and in this position pressed (through other paper) all over with the hand, so as to make a small quantity of oil adhere to its surface. Then it is taken out and placed care-

fully on white paper; another sheet is placed above (since two impressions can be taken), and the plant is pressed as before. On now removing it an invisible image remains on the paper. You sprinkle over this a quantity of blacklead (or ashes, &c.), and distribute it in all directions, as in applying sand to writing; the image then appears in all its parts. With an assortment of colours the natural colours of plants may be reproduced. To obtain fixity, resin is added to the black-lead (previously) in equal quantity; the impression is fixed when it is exposed to a heat sufficient to melt the resin.

THE GOLDEN FRITILLARY.

(FRITILLARIA AUREA).

This species is one of the prettiest of an attractive genus of hardy spring-flowering bulbs, but it is still very rare in cultivation, and scarcely known in this country. Indeed, Mr. Baker, in his monograph of the genus, in the "Proceedings of the Linnean Society," united it with *F. lutea*, but a subsequent examination of living plants has induced him to accord it specific rank. It certainly approaches the species named in habit and general character; having, however, a more broadly bell-shaped flower, besides the difference in colour. Dr. Kotschy discovered this handsome plant some years ago in the Taorus Mountains in Cilicia; and Schott described it in the "Oesterreichisches Botanisches Wochenblatt" for 1854, presumably from dried specimens, as no mention is made of its being in cultivation. Possibly he may have had living plants before him, though he gives only a short Latin description. Be that as it may, last year Dr. Regel figured and described it in the "Gartenflora." From specimens sent to him by Mr. Max Leichtlin; and the same gentleman has introduced it into this country. It is a dwarf plant, those described by Regel being about 6 in. high; but they were grown in pots. The lower part of the stem is naked, and beneath the solitary, terminal, drooping flower there is a cluster of from eight to ten narrow, somewhat glaucous leaves, from 2 in. to 3 in. long. The flowers are 1 in. deep, and of a rich yellow to both inside and out, and sprinkled over with small black spots. From the climate of its native habitat it will doubtless prove hardy in this country.

W. B. H.

Flower Shows and their Influences.—Is not showing becoming a trade and regarded by competitors as a means of making money? Are not Societies, by overbidding each other for "popular" support, animated by selfish motives rather than basing their action on the higher principles of promoting art? To speak plainly, is not horticulture being degraded to profitable purposes? Look at the programmes which are being sown broadcast. They stake their very existence almost on the chance of their fixture being a fine day. They have no reserve fund—cannot afford one—and, what is more, cannot safely exist without one. How many Societies have fallen and Exhibitions ceased to exist by risking their all on the chances of a fine day, and the day has proved rainy? They had no guarantee fund, they pledged their income before receiving it, and the end was a collapse. Is not showing being overdone—the hobby-horse being ridden too fast—the mania approaching a surfeit? Shows are becoming too common, and onsets but the counterpart of another. I now allude to the London Shows. A regular visitor to these not only knows almost to a certainty who will win the respective prizes, but what the plants will be which compose the groups. There is a sameness in these Shows which palls on the appetite; and how tired the reporters must be of repeating themselves! I should like to hear what they think about this subject, for I should imagine that few can form a better opinion of "Show and showing" than these gentlemen.—"Journal of Horticulture." [We very much sympathise with these views; the numerous Shows are becoming a real infliction to horticulturists about London. Shows are now of very doubtful effect on gardening; the real tests of the gardener's skill and taste are in the garden and not at the "Show," and the decadence of the great flower-shows is by no means an unimixed misfortune for horticulture.]

Another New Park for Birmingham.—At a special meeting of the Birmingham Town Council last week, the Mayor (Alderman Chamberlain) read a letter announcing the gift to the town of another fine estate for the purpose of a public park by Miss Ryland, the donor of Cannon Hill Park and of other valuable local gifts. It seems that a short time ago Miss Ryland was asked to sell to the Corporation some 42 acres of land situated at Small Heath, where the Council was desirous of opening a new park. Miss Ryland, in reply, decided to sell the land, but expressed her willingness to give it to the town for a term of 500 years at a peppercorn rent, subject to the application of the rents until the termination of the present lease, which has four years to run, towards the laying out the land as a park. The estate, which is beautifully wooded, is situated two miles and a half from the centre of the town, but well within the borough boundary, and in a quarter where the artisan class predominates. The intrinsic value of the gift was estimated by the Mayor at not less than £30,000. Cannon Hill Park, for which the town

is indebted to the same lady, is larger, embracing some 60 acres of undulating and well-timbered land, of the estimated value of £70,000.

Influence of Light on the Growth of Plants in High Latitudes.—In a valuable treatise on the vegetable productions of Norway, which has been published by Dr. Mueller, some extraordinary facts are related respecting the influence of the long duration of light during the summer months on the growth of vegetables in the higher latitudes in Norway. At 70° N. it was found that ordinary Peas grew at the rate of $\frac{3}{4}$ English in. in twenty-four hours for many days in a row, and that some cereals also grew as much as 2½ in. in the same time. Not only is the rapidity of growth affected by the constant presence of light, but those vegetable secretions which owe their existence to the influence of actinic force on the leaves are also produced in far greater quantity than in more southern climates, since the colouring matter and pigment cells are found in much greater quantity, and the tints of the coloured parts of vegetables are consequently deeper. The same remark applies to the flavouring and odoriferous matters, so that the fruits of the north of Norway, though not equal in saccharine properties, are far more intense in flavour than those of the south.

NOTES AND QUESTIONS—VARIOUS.

The Earliest Strawberry.—*La Grosse Sacrée* is the earliest Strawberry with which I am acquainted. I gathered ripe fruit of it from the open border to-day (June 12), which may be considered very early for this late season. It has a robust constitution, and is a free bearer, but it is not (as its name would imply) one of the sweetest type; still it is excellent in quality.—W. WILSON'S *Heckfeld*.

Hen-and-Chickens Daisies.—I see a note in last week's *GARDEN*, which reads to the effect that there is but one variety of Hen-and-Chickens Daisy; I send herewith a few flowers of two varieties, which are growing at Tottenham. There is a third variety which I have not seen for years; it is white, and I think even more prolific than the two varieties which I enclose.—A. J. PEARSE. (The varieties sent have the smaller flowers well thrown out from the large central one, and are very handsome—one delicate pink, and the other mottled red.—Ed.)

Gardens in the South of France.—I was some days at Monaco a month ago, and certainly I wish you, and all who care for flowers, could have seen the *Scarlet* and *ivy-leaved Pelargoniums* in masses of flower, the latter sometimes in cascades of 10 ft. or so over the cliffs in the old town garden, which is so much more beautiful than the Casino at Monte Carlo; there is also a shrub you should recommend very highly, when grown in a slightly peaty compost—the *Abutilon cultriforme* at Nice and Cannes its masses of pale yellow flowers, with large red calyxes, made a charming effect, and quite unlike anything else.—B. H. W.

Porons Glazed Pots for Strawberries.—I should like the opinion of some of your readers respecting the desirability of using glazed pots for Strawberries. They are such thirsty souls that it tries my patience to supply them with water—my belief is that glazed pots would answer. Have they ever been used for such Strawberries, and if so, with what result?—OSBEYAN.

The Double Buttercup.—This showy flower is very common in cottage-gardens about here. It may not be generally known that it is necessary to lift the roots in autumn and keep them under cover; if left in the ground, they never perish on the worst soils, but as there are various sorts it might be interesting to know to which "South Wilts" refers.—Ed.

Rare Lilies.—The following are now in bloom in the Bulb Company's grounds at Colchester, viz., *Lilium Kramerii roseum*, *L. calcosum*, and *L. pulchellum*. These are at present in beautiful condition.

Libertia grandiflora, pulchella, and ixioidea.—I have all these three species now in bloom; they are graceful and elegant plants, but *L. grandiflora* is the only one sufficiently over to find favour with the general public. I do not find them hardy enough to stand the winter in the open border with any certainty of success, but they do very well in pots in a cold and rather deep glazed pit. In fact they much resemble a *Carex*, whilst their snow-white flowers remind one strongly of a *Libertia* *Carex*, *Tring*.

Rubus deliciosus.—I have here can I purchase this Bramble? Will it succeed under the shade of trees?—A. M. D. [We believe it is distributed under our more important trees and shrub nurseries; we have no doubt that it will succeed under the shade of trees, though we have not seen it in such situations.]

Best Early Kidney Potatoes.—We have something like a dozen named varieties of these Potatoes, many of which differ in name only, the best among them for earliness, productiveness, and exhibition purposes is *Rivers' Royal Ashleaf*. This day (June 10th) we have tried most of them, and this is the decision at which we have arrived.—B. GRUBBS, *Essexley*.

London Commons and Parks.—The Metropolitan Parks and open spaces are just now looking at their best. Londoners should visit the pretty common of Tooting Beck and Tooting Graveney, the grand heaths of Blackheath and Hampstead, and the parks at Rotherhithe and Finsbury. During the past twelve months, under the direction of the Metropolitan Board of Works, considerable alterations have taken place in these several pleasure resorts, which, we fancy, the numbers who visit them will appreciate.—"Metropolitan."

A Strawberry Land.—As we write, Strawberries are yet so very high priced in Covent Garden that the following extract from the "Californian Horticulturist" reminds one forcibly of the drawbacks of our climate:—"About the 1st of this month (May) Strawberries arrived in considerable quantities, and the price came down to 15 cents per quart. Of course, it was much improved; the colour of the sort—Longworth Prolific—always the first in the market, had assumed its usual richness and deep red, its size the customary large dimensions, and the flavour its wonted goodness and sweetness. What an admirable assistance to health and this delicious is this delicious fruit except Oranges, Apples, and Bananas, of which we have become almost tired."

No. 240.] SATURDAY, JUNE 24, 1876. [Vol. IX.

“This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE.”—*Shakespeare.*

THE GROVE AT TEW PARK, OXON.

TEW Park will long be interesting, from the fact that it was there J. C. Loudon practised agriculture before he began writing the works which were such a marked addition to the horticultural literature of England. The present short notice, however, will not concern Loudon's planting, or other work of his of which there is much that is interesting, but merely refer to a part of the grounds called the Grove, where one of the earliest examples of the wild garden has been successfully formed. The Grove is a plantation of remarkably fine trees, bordering a wide sweep of grass, which varies in width. This grove, unlike much of the rest of the ground, does not vary in surface, or but very little, so that one of the greatest aids to the wild gardener is absent. Originally this now pleasant grove was a dense wood, with Gout-weed mainly on the ground, and troublesome flies in the air. A few years ago the formation of a wild garden was determined upon, and the first operation was the thinning of the wood; light and moving air were let into it, and weak or overcrowded trees removed. This, so far, was a gain, quite apart from the flowers that were in good time to replace the few common weeds that occupied the ground. Of these the unattractive Gout-weed was the most abundant, and the first thing to do was to dig it up. It was found that by deeply digging the ground, and sowing the wood Forget-me-not in its place, this weed disappeared—a great advantage. Who would not exchange foul weeds for Lilies of the Valley, Wood Forget-me-nots, and many other plants possessing equal charms! The effect of broad sheets of this Wood Forget-me-not (*Myosotis sylvatica*) beyond, and seen above the long waving Grass gradually receding under the trees, was very beautiful; now, however, its beauty is not so marked as earlier, when the colour was fuller, from the plants being more compact; but one charm of the wild garden is that the very changes of plants from what may be thought their most perfect state, may be in itself the source of a new pleasure instead of a warning, such as so often occurs in the garden, that we must cut them down or replace them.

Not to mow is almost a necessity in the wild garden: considering that there is frequently in large gardens much more mown surface than is necessary, many will not regret this need. Here the Grass is designedly left unmown in many places, and thereby much labour is saved. Of course it may be cut when ripe, and most of the spring flowers have past and their leaves are out of danger; even in parts where no flowers are planted the Grass is left till long enough to cut as meadow. Except where actually required as a carpet, Grass may often be allowed to grow even in the pleasure ground; quite as good an effect is afforded by the unmown as the mown Grass—indeed, better when the long Grass is full of flowers. Three-fourths of the most lovely flowers of cold and temperate regions are companions of the Grass—like Grasses in hardness, like Grasses in summer life and winter rest, like them even in stature. Whatever plants may seem best to associate with in gardens, an immense number—more than two thousand species of those now cultivated—would thrive to perfection among our meadow Grasses, as they do on the Grassy breast of the mountain in many lands. Some, like the tall Irises or Columbines, will show their heads clear above the delicate bloom of the Grass; others, like the *Cerastiums*, will open their cups below it, in this way multiplying the variety of effects that may be obtained. The varieties of Columbine in the Grass were perhaps the prettiest flowers at the time of my visit. The white, purplish, and delicately-variegated forms of this charming old plant, just seen above the tops of the long Grass, growing singly, in little groups, or in spreading colonies, were sufficient in themselves to form a wild garden for June. Established among the Grass they will henceforward, like it, take care of themselves. The rosy, heart-shaped blooms of the *Dilytra spectabilis* are recognised at some distance through

the Grass, and, so grown, furnish a bright and peculiarly pretty effect. Tree Peonies succeed admirably, and their great heads of flower quite light up this charming wilderness. Plants of the Goat's Beard *Spiræa* (*S. Aruncus*) are very stately and graceful, even now before their flowering, being quite 6 ft. high. In a few weeks, when the numerous flowers are open, they will present quite another aspect. In the wild garden, apart from the naturalisation of free-growing exotics; the establishment of rare British flower is one of the most interesting occupations; and here, under a Pine tree, the modest, trailing *Linnaea borealis* of the northern Fir-woods is beginning to spread. The Foxglove was not originally found in the neighbourhood; now the ordinary kind and the various other forms of this fine wild flower adorn the woods. In this way also the Lily of the Valley has been introduced and is spreading rapidly. Many climbing Roses and various other climbers have been planted at the bases of trees and stumps, but, though thriving, the plantation is as yet too young to show the good effect that these will eventually produce. There is no finer picture at present to be seen in gardens than a free-growing flowering creeper, enjoying its own wild way over an old tree or stump, and sending down a rain of flower-laden shoots. A *Clematis montana* here, originally trained on a wall, sent up some of its shoots through a tree close at hand, where, fortunately, they have been allowed to remain, and now the long shoots hang from the tree full of flowers. The large plumes of the larger hardy Ferns are seen here and there through the trees and Grass, and well they look—better here among the Grass and flowers, partially shaded by trees, than in the hardy Fernery, which is so often a failure, and when a success, often “too much of a muchness,” so to say. The wild garden of the future will be also the true home of all the more important hardy Ferns. The rivals of the Ferns in beauty of foliage, the *Ferulas*, and various other umbelliferous plants with beautifully cut foliage, have also their homes in the wild garden. The Welsh Poppy thrives, as might be expected, admirably in the grove, its rich yellow cups just showing above the meadow.

In another part of the grounds there is a raised walk quite away from trees, open and dry, with sloping banks on each side. This may be called a sun-walk, and here quite a different type of vegetation is grown; Scotch Roses, Brooms, Sun Roses, Rock Roses, &c. It is quite recently formed, and will probably soon accommodate a more numerous and interesting flora. Such an open sunny walk, with dry banks near, is a capital position in which to carry out various charms of the wild garden. Peculiarly suitable, however, in such a position is a good illustration of the vegetation of the hot, rocky, and gravelly hill-sides of the Mediterranean region, and this is quite easily represented, for the various leguminous plants and dwarf Pea-flowered shrubs, such as the Spanish Broom, many of the beautiful Rock Roses (*Cistus*), the Sun Roses (*Helianthemum*), and the Lavenders will, with a host of companions, for the most part thrive quite as well on a sunny bank in England as in Italy or Greece. In the wild garden it is easy to arrange aspects of vegetation having a geographical interest, and a portion of such a sunny bank as I allude to might be worthily furnished with the various aromatic plants (nearly all hardy) which one meets with on the wild hill-sides of Southern France, and which include Thyme, Balm, Mint, Rosemary, Lavender, and various other old garden favourites.

There are various other parts of the garden here of which we might speak with advantage, but at the present time they are undergoing change, and there is every prospect that the gardens here will one day be even much richer than at present in all that interests lovers of Alpine and hardy flowers, as both Mr. Boulton and his able manager, Mr. Macfarlane, admire these, and are making good preparations to grow them well and also in a picturesque manner. The Edelweiss (*Leontopodium alpinum*), so often regarded as difficult to cultivate and difficult to obtain, is really not so hard to manage, and we noticed a healthy tuft of it in a border here bearing numerous flower-heads larger than one notices on the Alps. Gentians (*verna* and *acaulis*) are planted out here in the turf in one of the old enclosed gardens, and, so far, with a good result; the soil is made deep for them—3 ft.; there is plenty of Oxford

gravel in it. The Grass is of course kept low till such times as they themselves form the turf. W. R.

THE SAXIFRAGE.

PERHAPS this genus, many of which are now in flower, includes more true Alpine flowers than any other. In the Arctic Circle, in the highest Alpine regions, on the arid mountains of Southern and Eastern Europe and Northern Africa, throughout the length and breadth of Europe and Northern Asia, they are found presenting many interesting varieties of form and colour. From their Alpine habitats one might expect these to be as difficult of cultivation as other Alpine plants, but they are the easiest to grow of all. Hence they were common in collections of Alpine flowers when few other families were represented in them. Of late years many very pretty species have been introduced, and so great are the variety and merit of the family now that a very interesting garden might be made of its members only. For purposes of cultivation some kind of rough division of the members is convenient, as they are so different in aspect and uses. The most ordinary form is the Mossy or Hypnoideus section, of which there are many kinds in cultivation. Their delicate, Moss-like, spreading tufts of foliage so freshly green, especially in autumn and winter, when most plants show decay, and their countless white flowers springing from this carpet in spring make them very precious inhabitants of gardens. These Mossy kinds are especially suited for the tasteful practice of carpeting the bare ground beneath taller plants. They are also admirable for their fresh green hue, with which they clothe rocks and banks in winter. They are indeed the most precious winter "greens" in the Alpine flora. Next to these we may place the very extensive silvery group as represented by such kinds as *S. aizoon* and the great, pyramidal-flowering *S. cotyledon* of the Alps. Considering the freedom with which these grow in all cool climates, even on the level ground, and their beauty of flower and of foliage, they are perhaps the most precious group of Alpine flowers we possess. Anybody with a cottage garden can grow them. The London Pride section is another of great beauty in its way. These thrive under ordinary circumstances in lowland gardens, &c., even soon naturalise themselves in lowland woods and copses. But the most brilliant Saxifrages, so far as flower is concerned, are the Purple Saxifrage (*S. oppositifolia*) group and their near allies. Here we have tufts of splendid colour in spring with the same dwarf and the most perfect hardiness. The large, leathery-leaved group, of which the Siberian *S. crassifolia* is best known, are also of much importance; their constitution is such that they thrive in ordinary soil and on the level ground; there are various other minor groups. Such of the smaller and rarer Alpine species as require any particular attention should be planted in moist sandy loam mingled with grit and broken stone, and made very firm. Very dwarf and rather slow-growing kinds, like *S. cæsia* and *S. arctioides*, should be surrounded by half-buried pieces of stone, so as to prevent their being trampled on or overrun, and stone will also help to preserve the ground in a moist healthy condition in the dry season when they are most likely to suffer. Very dry winds in spring sometimes have a very bad effect on Saxifrages when some such precautions are not taken. When in established tufts they are apt to throw out stem-roots into their own cushions, so to say—cushions frequently moist during the autumn and winter months. When the tufts are suddenly dried, the plants suffer if the ground roots be dried too. V.

Double Buttercups.—I enclose a bloom of the double Buttercup to which I alluded (see p. 584), it is very common in the cottagers' gardens hereabouts. I presume it is a variety of the Turkish or Turban Ranunculus. It is a very handsome showy flower, with a good habit, being compact and dwarf, and in a cool, shady border it will last in bloom for three or four weeks; at a distance it looks almost as showy as an Aster or French Marigold. The other common double Buttercup in the gardens here is hardy enough, and has a showy flower, but it is stalky and weedy-looking in habit, though doubtless pretty and showy in a cut state.—G. B., *South Wills*. [What you have sent is a Persian Ranunculus.]

THE FUCHSIA-FLOWERED RIBES. (*RIBES SPECIOSUM*).

This plant has long been in cultivation in this country, and is so distinct from all its congeners that it well deserves a place wherever a few feet of a sunny wall can be spared on which it can be trained. It closely resembles the common Gooseberry in habit of growth, but the flowers are much larger and quite distinct in shape and colour. Professor Asa Gray recently described this plant in the "American Naturalist," whence we extract the following account of it:—"The Scarlet-flowered Gooseberry of California is so distinct that a separate section has been provided for it. Besides the bright colour and ample size of the flowers, its calyx-lobes do not turn back, and are often only four; the stamens protrude for an inch or more, and the rather dry berry is few-seeded. Its synonyms are characteristic: *R. stamineum*, of Smith, for the remarkable long stamens; *R. fuchsoides*, of Berlandier, for the resemblance to a Fuchsia blossom. It is hardy in England, and is prized in cultivation for its brilliant red flowers, garnished by the shining and almost evergreen leaves. Trained to the wall of a house it may be carried to the height of 15 ft. or 20 ft." It is now in flower, our life-sized illustration of which represents

Fuchsia-flowered Ribes (*Ribes speciosum*).

one joint of a slender spray sent by a correspondent, who remarks that he found it in an old cottage garden. We have seen it cultivated as a wall shrub in Scotland, but it does not appear to be grown in modern gardens so much as its merits demand. B.

The Showy-flowered Bramble (*Rubus spectabilis*).—The leaves of this elegant shrub are alternate, and of medium size, with three leaflets, which are ovate, acutely-pointed, doubly and unequally serrated on the edges, and downy beneath when young. The stems are shrubby, round, smooth, or without prickles, and somewhat flexuose. The flowers are large, of a beautiful dark purple, scented, and produced singly on longish, terminal foot-stalks, just as the leaves begin to unfold, a time at which they are very conspicuous. The fruit is large, bright yellow, acid, and when ripe in June and July, excellent for tarts, but not produced in sufficient quantity to be available for that purpose, as it is only produced singly at the end of the lateral growth. This Bramble is a native of the North-west coast of North America, and forms a thinly-branched, hardy, deciduous shrub, from 4 ft. to 5 ft. high, with many stems, rising more or less annually from the ground. When adorned in April and May with its large, showy, dark purple flowers, it has a very elegant appearance, and in July, when its large yellow fruit is ripe, it forms an equally striking object. It grows freely in any common soil, and is readily increased by the means of spreading underground suckers, which are produced rather too freely if the soil in which it grows be rich, and when such is the case, it requires to have a portion of them removed every season to keep the plants within bounds. The old flowering stems also require occasionally to be cut out to make room for the younger ones. It was first introduced in 1827 by Douglas.—G. GORDON.

THE KITCHEN GARDEN.

TRANSPLANTING VEGETABLES.

In garden culture it is often necessary to transplant many crops from the seed-beds to their allotted quarters. This is not the best plan, however, in many cases—seldom is, in fact; and there are some vegetables that can hardly be transplanted successfully at all. The effect of transplanting is to check the growth, and generally to reduce the bulk of the produce, whatever it may be. Take Lettuces, for example. It is usual to sow them in beds, and afterwards to dibble them out in rows 8 in. or 9 in. asunder. This practice is all very well in good hands, and under generous culture; but should the weather be dry when the plants are moved, which is often the case with the vegetables of which frequent successions have to be sown, or if the plants be allowed to get too old before lifting, carelessly planted, or put into a poor soil, the chances are much against the crop being a good one, or the plants bearing or making those tender and succulent leaves which make the Lettuce so acceptable as a salad. The early varieties, such as the hardy Hammersmith, will hardly transplant at all without running directly to seed; but when sown in drills, and afterwards thinned, it is still one of the tenderest and most useful Lettuces we possess, for it will stand the most severe winters with impunity, and what is true of this kind is more or less true of all the others. It is always best to sow where the plants are to remain. Early crops may be sown twice as thick as they are intended finally to be; and every other row can be drawn young for spring salads and other purposes. We find such young and tender seedlings are just as much appreciated in the kitchen and pantry as hearted Lettuces; and as they come in when the winter and forced plants are nearly over, they form an excellent stopgap. Of the effects of transplanting upon Cauliflowers every cultivator is aware. "Buttoning," which is so apt to occur, in summer crops particularly, would hardly ever happen if the plants could be sown where they are to remain. This is sometimes done when the ground is vacant, and the time can be spared to prepare the ground, certain crops and fine heads being almost invariably the result. When the ground is dug for Peas, or Scarlet Runners, for example, which are usually cropped between with Cauliflowers, it is often as convenient to sow the seed as to transplant, and but very little time, if any, is lost. The seed should be sown as the ground is dug, just a pinch every 2 ft. or so, and in one or two rows, according to the width between the rows of Peas; and when the plants come up, they should be thinned away to one to each patch, and earthed up as they grow. Wherever blanks occur among other crops for which the ground has been prepared, it will be found a good plan to sow Cauliflowers in this way, to guard against failures in transplanted crops. I do not recommend the plan for autumn-planted Cauliflowers under handlights, however, for they are not so apt to button, and the transplanting hardens them against the winter; neither is it an advisable practice with winter Broccoli, for they can seldom be got to head soon enough, and a check is beneficial to them in the event of a severe winter. Of course, the effect of transplanting is the same with all the Brassica tribe. Those who want very large Cabbages and Savoy's can best secure them by sowing the plants where they are to grow. It is in this way that Cabbages produce those specimens we sometimes see at exhibitions. All the Cabbage tribe are tap-rooters, and if not transplanted they send their roots down deep into the moist soil, and are able to stand the driest summer, unless the soil be naturally thin; whereas, if moved at the seedling stage, the roots are broken, and never penetrate the ground very deeply afterwards. With Turnips transplanting is out of the question; but Carrots will move, if the operation be performed with care when the plants are young—just in the rough leaf. They must be got up with all their roots, which should be dropped straight into a deep hole made with the dipper, and filled in around with fine soil from the top. In this way the tap-root is placed in its natural position, and the Carrot will grow and fill the hole. Indeed, we have heard of very fine and symmetrical examples being grown by transferring young plants in the above manner to wide holes filled with sand; but the practice is not to be recommended, except to make up

blanks, and then only when it is too late to sow seed. With the same care Parsley may also be transplanted in a young state. Moist weather should be chosen for the work, and watering and stirring the soil in dry weather must not be forgotten till the plants are established. Beetroot transplants more successfully than either Carrots or Parsley; and, though the roots are apt to be forked, they are often good and fit for use. We have not unfrequently seen good roots got from amongst plants which have been used in the flower-beds, though they had not been put in with great care. As with the others, it must be moved when young, and before the root begins to form. All the Bean tribe will stand transplanting. Kidney Beans may be forwarded considerably by sowing first in boxes or pots, and afterwards putting them out. In late situations this is the only plan to get crops early, and blanks in the later sowings should always be made up with plants from the most crowded places. Broad Beans may be similarly treated; but in both cases the transplanting must be done before the plants make the second rough leaf. Peas may be moved without fear, either singly or in bundles, when they are 2 or 3 in. high, and failures among the rows can generally be made up in this way, though, as often as otherwise, such a thing is never thought of it is not necessary to make a continuous row in such a case, but only to put in a bunch of plants every foot or so, and these will meet on the stakes and make a good row. Peas are, in nine cases out of ten, sown too thickly, and there are always plenty, if the seed be at all good, to be had for transplanting purposes. Of course the practice of sowing in heat in pots, boxes, or on turves, as for early crops, is well understood by all good cultivators. Leeks transplant easily; but we prefer to sow and thin, and afterwards earth up, so as to have good roots soon without much trouble. Onions, both winter and spring sown, are frequently transplanted. With the former the work should be done early enough in autumn to enable plants to get hold of the ground before frost sets in; or, what is better, it may be deferred till spring, but not till the bulbs begin to form; blanks in summer crops should be made up at the thinning stage. In all cases, see that the long roots are carefully lifted with the plants, and that they are dropped perpendicularly into the hole and covered up to the base of the bulb, and no further; it matters little if the plant does fall over on its side for want of support, it will grow and bulb well enough. The Seakale does not transplant well even in a seedling state; I have tried it on several occasions to fill up vacancies, but with only indifferent success. Those, therefore, who, like myself, grow their plants from seed to force annually, should sow thick enough to ensure a crop. One thing, with regard to transplanted crops of Lettuce, Cauliflowers, &c., may be mentioned, and that is, that slugs do not attack them so much as when the plants are sown where they are to remain. I have noticed this often, and attribute it to the latter being more tender in the tissues, and therefore more palatable to slugs.

CHEF.

Early Peas.—With me Laxton's Unique, the best of all really dwarf Peas, is earlier than the Shah, of which Mr. Gilbert speaks so highly. Unique has done remarkably well this season, having been sown out in the open ground and thus escaped the attacks of birds. The haulm—now covered with Peas as large as those of William I. and as green as Grass—is about 16 in. in height, and can be grown without sticks at 2 ft. apart. On warm early borders Unique is unsurpassed as an early dwarf Pea. The Shah bears a close resemblance to King-leader in all points; the pods are shorter and lighter in colour than those of Unique. The latter is just the type for the hybridist to work upon, and if Mr. Laxton could succeed in impressing it with more of the quality of his Omega—one of the best late dwarf Peas which we have—than it possesses, he would have made a good step in a right direction. There is yet room, in spite of the present wealth of early Peas, for the production of a really hardy and first early Marrow, having the fine qualities of the best wrinkled kinds but harder. A round Marrow is invariably harder than a wrinkled kind, and is preferred by growers for market. Mr. Laxton's Supreme has for some time been a favourite market kind, and William I. and Omega are fast coming to the front.—D.

Celery Trenches.—Where trenches for Celery or Peas are taken out before they are wanted for these crops it will be found advisable not to dig up the bottom of the trenches till they are required. The former takes root more quickly, and the latter germinate under such conditions in a shorter period than they otherwise would do.—R. P. B.

NOTES OF THE WEEK.

SWEET PEAS IN POTS.—These are now seen in abundance in the London flower market, and are well worthy of some attention in private gardens. If well grown they are very useful and welcome, especially earlier in the year, before Sweet Peas bloom out-of-doors.

PHILADELPHUS LAXUS.—We are indebted to M. Lavallée for blooming specimens of this fine hardy shrub, gathered in his famous collection at the Château de Segrez. The individual blooms are very large and gracefully disposed on the branchlets. It will prove to be an important addition to our best flowering shrubs.

THE ROYAL BOTANIC GARDEN SHOW.—There was such a numerous and brilliant gathering at the Royal Botanic Gardens, in the Regent's Park, on Wednesday last, that one was reminded of the old meetings of the society in its most prosperous days. There is no garden now existing so suitable for flower shows, and hence the regret that it is not as satisfactory as regards cultivation and interest as it is in landscape beauty.

EARLY STRAWBERRIES.—Mr. Thomas Malpass, Usk, Monmouthshire, writes to us respecting this subject as follows:—"I do not consider La Grosse Sucrée so early as Cuthill's Black Prince. Of that I gathered 2 qts. on the 8th of June, in the open ground off 100 plants: and up to-day (June 21) have gathered in all 15 qts. I have always found this to be the earliest and best Strawberry for early work, both out-doors and indoors."

THE CANTERBURY BELL AS A POT PLANT.—Plants of this old favourite are now abundant in the market for "furnishing," *i.e.*, house decoration. They are of marked value for this purpose, being, when well-grown in 6-in. pots, nearly 3 ft. high, bold in habit, their large flowers showing a variety of attractive colours—delicate pink, pure white, violet-purple, pale lilac, and others. The plants are kept out-of-doors all the winter, and transferred from the open air to the market benches.

EARLY SUMMER KIDNEY BEANS.—These mostly come now from the Channel Islands, the Canadian Wonder being a popular sort and grown to a large extent. The best kind, however, received at this season, and earlier, from the Channel Island gardens is the Improved Syon House.

THE PEACH-LEAVED HAIR BELL FOR CUTTING.—When gathered from well-grown plants the flowers of the various forms of this fine hardy plant are admirable for cutting, and are highly esteemed in the London market, especially the white single forms, of which there is one with a very faint shade of lilac. The most vigorous blooms are obtained from plants occasionally divided and replanted in fresh rich ground.

THE SCARLET STRAWBERRY.—This old kind, the best of all for preserving, and brought in considerable quantity to the London markets for that purpose, would probably repay attention as a table fruit. Its earliness and good flavor would go far to compensate for its small size. At Isleworth it is grown extensively under the orchard trees, under conditions not likely to fully develop its good qualities.

MANLEY HALL GARDENS.—In these famous Manchester gardens a large winter garden will shortly be erected, and the whole re-arranged as a public resort under the management of Sir E. Lee, of Alexandra Palace. Mr. McKenzie is the horticultural director and designer of the winter garden. There are so many fine features already in these gardens that a well-directed attempt to convert them into a public establishment could hardly fail to succeed, and the results, too, to the public should be more useful and instructive than those that usually flow from public gardens as now organised.

DAPHNE RUPESTRIS.—Messrs. Backhouse writes to us from the York Nurseries calling attention to the omission of this dwarf Alpine species from the article on Daphnes published in THE GARDEN last week. They speak of it as surpassing the well-known trailing sweet-scented *Daphne Cneorum* both in beauty and fragrance. It has erect shoots, and forms dense, compact tufts, 2 in. high, and a foot or more across, covered with a mass of bloom which sometimes almost eclipses the plant. Its colour is a soft shaded pink or rose, and its flowers are individually larger and more waxy than those of *D. Cneorum*, but forming clustered heads in the same way. It is essentially a rock-plant, growing wild in fissures of limestone in peaty loam. It is perfectly hardy, and of easy culture.

— A NEW nursery and seed firm has started in Edinburgh under the designation of Ireland and Thomson. The senior partner is Mr. J. S. Ireland, formerly manager of the seed department of Messrs. Methven and Sons, and the junior partner, Mr. D. W. Thomson, son of Mr. D. Thomson, Drumlanrig. Their nursery grounds are at Craigleith, Curly Bank, and their seed department will be carried on at 20a, Waterloo Place, near to the Waverley Station, Edinburgh.

THE FLOWER GARDEN.

HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

NEVER before were so many Moccasin-flowers (*Cypripedium* spectabile) seen about London as at the present moment. In Mr. Wilson's garden, at Kew, at Rollinson's, and in many other gardens, the handsome flowers of this plant add a novel charm to the scene. The abundance of it is mainly owing to large importations during the past winter. There is now enough in the country to suffice for generations if the plant be properly cultivated; most people know that it loves peat, but few keep the peat moist enough; dry peat is starvation to it, especially near trees where the little moisture is absorbed by the tree-roots. It should be borne in mind that this *Cypripedium* is a bog plant, and that in this country it thrives best in deep, moist peat or vegetable soil. If grown in a few gardens here and there, so well as at Glasnevin, it would soon become an established herbaceous plant. It is finely grown in a bog in Mr. Latimer Clarke's garden at Sydenham, and nothing could exceed the stately beauty of the plants we have lately seen there. In Mr. Clarke's group there is one with quite a deep rose lip, which looks quite showy beside its fellows. The common Forget-me-not is well worthy of culture, the colour being deeper and the individual blooms handsomer than the two earlier kinds. It is quite at home in moist borders. The most effective flowers of the season are the Foxgloves—the common kind and the white and spotted varieties—which are so stately in the shades of the wild garden, where single plants or groups last much longer than they do in exposed borders or beds. Among Alpine flowers the gem of the week is the Alpine Pink (*Dianthus alpinus*), the large gay blossoms of which stand up so sturdily from its dwarf cushion of shining green leaves. It is grown as a border plant in Mr. Latimer Clarke's charming garden at Sydenham. Fischer's Pink (*Dianthus Fischeri*) is also smothered in bloom; it is very dwarf and showy, and should rank among the choicest Alpine plants. The old double Yellow Rocket, now so seldom seen, has been a very effective plant for the past few weeks; it is usually seen in a somewhat feeble condition, and few, we fancy, have any just idea of its value, but we have seen several tufts during the past week nearly 3 ft. high, and bearing many spikes of double yellow blossoms. It is a precious border flower, and should be more extensively grown, being probably a better perennial than the ordinary double Rockets, which are so seldom seen now. *Papaver nudicaule* is very showy on light soils, where it grows freely and often "sows itself." The Ragged Robin (*Lychnis flos cuculi*) is singularly pretty by the side of water, in small islets, &c. The London Pride type of Saxifrages seem to thrive well in the shade, and are now pretty in woods where they are established. The old and of late seldom seen *Liris Pavonia* is beginning to appear more frequently in London gardens, and such a singularly pretty flower is welcome: it loves sandy or peaty soil and sunny warm spots. The Delphiniums and Potentillas are beginning to show effectively in the garden landscape. Double Pyrethrums are very showy where well selected; the Hairbells are beginning to blossom, and the white variety of the common *Tradescantia* is very beautiful. Among Alpine flowers the Rocky Mountain *Epilobium obovatum* is a gem, and the true Alpine Poppy, in several varieties, is yet opening freely its fragile blossoms.

A Primula for Window Gardening.—Among several plants that I have tried inside a London window, I have found none succeed better than one of my most recently-made floral acquaintances— I mean *Primula verticillata*, which, with its head of bright canary-yellow flowers rising on a slender stalk from a rich tuft of leaves of hoary, glistening whiteness—is now a very pleasing object, and forms a striking contrast to many town-bred Fuchsias and Pelargoniums. I had the plant of it last December, and with but little care, letting it have regular moisture, it developed itself healthily through the winter, and is now in full flower. I imagine it is rather late, in consequence of having had a good deal of growth to get up, it having been a very small plant when I first received it. Its late flowering is, however, an advantage in my case.—H. N. H.

Ragged Robin (*Lychnis flos cuculi fl.-pl.*)

Fringed Pink (*Dianthus superbus*).

Common Foxglove (*Digitalis purpurea*).

Gypsophila Steveni.

Gypsophila elegans.

Erect Clematis (*C. erecta*).

Yellow Monkey-flower (*Mimulus luteus*).

Canterbury Bell (*Campanula Medium*).

Showy Sculum (*S. spurium*).

Marsh Forget-me-not (*Myosotis palustris*).

Peach-leaved Campanula (*C. persicifolia*).

Sweet William (*Dianthus barbatus*).

SOME HARDY FLOWERS OF THE WEEK IN LONDON GARDENS.

MOSS ROSES FOR MARKET.

ONE of my neighbours grows the Moss Rose largely for market; he has about two acres of it in various spots, some being on a warm border, sheltered from the north by a wall, others growing under orchard trees, and the remainder in open quarters. This arrangement is admirable, inasmuch as it admits of a lengthened season of cutting—the border plants furnishing the earliest bloom; these are followed by those under the trees, and the exposed plants come in latest. The common Moss Rose, so well known in gardens, is not largely cultivated, as it is neither robust nor free enough for market purposes, the sort most in favour is a deep red kind, perhaps a little less mossy than the common Moss, but the flowers are produced in great abundance, a strong shoot bearing seven or eight good buds, all of which will open well, but it is not desirable that they should be too much expanded before cutting, as the mossy surroundings of the flower are then less noticeable. The Moss Rose is cultivated much in the same fashion as the Raspberry, with this difference, that its old wood does duty for two or three years before it is cut away. Good, established plants are, however, so productive of young growth from the base that it is better to keep the bushes well thinned out, both of old wood and also of the weakest of the season's growth. No form of budding on any kind of stock could give the fine results obtained from these plants on their own roots. Ordinarily the Moss Rose thrives well under orchard trees, and probably there is no better paying under-crop, for with the shelter the overhanging boughs afford there is little danger from frost, although there is some harm resulting to the young growth in open quarters, when late white frosts prevail. As suckers are sent up so freely from strong stools, the plan of increasing the plants is to lift all the outside growths and plant them in rows, in clumps about 3 ft. apart, the rows being 4 ft. asunder. For the first two years dwarf-growing crops may be taken from between the rows, but after that the plants, if they have done well, will want all the space. During the winter the old wood is cut out, and, as I have said, also the weakest of the young growth; the robust shoots, too, are shortened back, the soil is lightly forked over, and a good top-dressing of long manure applied; thus treated, they remain until the buds are ready for cutting. A quarter of good established plants furnishes a large yield of bloom.

A. D.

Border Flowers that should be Sown now.—Bright weather having at last set in, hardy flower borders are every day becoming more interesting, biennials being largely in bloom and making a grand display. Sweet Williams, Canterbury Bells, Foxgloves, Columbines, Pentstemons, and many other summer-flowering plants, are at present in beautiful condition. Stocks of various kinds are just over; these have filled the garden with a rich perfume, and, succeeding the Wall-flowers and Violets, have kept the air deliciously sweet. By the expenditure of a small sum in seeds now it is possible to ensure a glorious display of hardy border plants next season. Those mentioned above are amongst the most popular of biennials, but there are numerous others just as easily grown, and as rich in perfume and beauty. Pansies of various hues sown now and planted out in the autumn will bloom most abundantly all through the succeeding summer.—A.

Eremostachys laciniata.—This stately border plant, which seems to be little grown, is now in flower with me, and is producing a remarkable effect. It is a member of the large and interesting family of Labiates. It has formed an erect, woolly flower-stem, about 6 ft. high, the upper portion, for some 2 ft. 6 in., having whorls of large purplish flowers (the lower lip dull crimson), 2 in. to 3 in. apart, and the lower part clothed with rich green, deeply-out leaves, gradually decreasing in size towards the base, which is surrounded by leaves much of the same character, but larger, more horizontal, and more deeply cut into segments; the fine, rich green, elegantly cut leaves form a fine base to the strong, whitish, very woolly flower-stem, and constitute one of the chief beauties of the plant. Such plants as this *Eremostachys* require room, but are very effective, and well worth growing, breaking up uniformity by their height, foliage, and peculiar colour, and catching the eye very readily, something like a church spire in a landscape. I may mention that this *Eremostachys* seems to like a light, rich, loamy soil; it is perennial and quite hardy.—W. W. S., *Worthing*.

CLASSIFICATION OF BAVARIAN PRIMROSES.

THE following is a list of our Primulas, with synonyms and varieties; perhaps it may be of interest:

- I. *Primula farinosa* (L.)**—Varieties—White, dark purple, *dendrata* (Koch.), *stricta* (Hornemann), *farinosa acaulis* (Backhouse), *sotica*.
- II. *P. longiflora* (Allioni).**
- III. *P. acaulis* (Jacquin).**—Syn. *P. veris*—*acaulis* (L.), *P. grandiflora* (Lamark), *P. sylvestris* (Scopoli). Varieties—1, flesh-coloured, fl.; 2, caulescens; 3, *acaulis* × *officinalis* (Muret); 4, *sub-acaulis* × *officinalis* = *brevistyla* (D.C.); 5, *subacaulis* × *officinalis* = *flagellioacaulis* (Kerner); 6, *acaulis* × *Columnnæ* = *Ternoviana* (Kr.); 7, *acaulis* × *elatiar* = *digena* (Kerner).
- IV. *P. elatiar* (Jacquin).**—Syn., *P. veris*—*elatiar* (L.). 1, var. *media* (Peterm.), *elatiar* × *officinalis*; var. 2, a yellow circle round the base of the flower; var. 3, with red flower.
- V. *P. officinalis* (Jacquin).**—Syn., *P. veris*—*officinalis* (L.); 1 var. *ampliata* (Koch); syn., ed. I.
- VI. *P. suaveolens* (Bertolon).**—Syn., *P. columnnæ* (Tenore); *P. Tomasini* (Gren. and Godetroy). Var., *P. inflata* (Lehman)—*officinalis* × *columnnæ*.
- VII. *P. auricula* (L.)**—Varieties—*ciliata* (Moretti) = *Balbisia* (Lehmann); *P. leucantha* (Hegetschweiler); *P. Göbelii* (Kerner)—*auricula* × *villosa*; *P. obovata* (Huter)—*auricula* × *tirolensis* (Schott); *P. venusta* (Host.)—*auricula* × *carniolica*; *P. discolor* (Leybold)—*auricula* × *Daonenensis*; *P. Portæ* (Huter)—*subauricula* × *Daonenensis*; *P. Arctotis* (Kerner)—*subauricula* × *hirsuta*; *P. pubescens* (Jacquin) *superauricula* × *hirsuta*. Syn., *helvetica* (Schleicher) = *raetica* (Gandin) = *alpina* (Reichenbach).
- VIII. *P. alpina* (Schleicher).** Syn., *P. rhætica* (Koch).
- IX. *P. pedemontana* (Thomas).**
- X. *P. villosa* (Jacquin).**—Schott, not Koch. Syn., *P. ciliata* (Schrank) = *P. hirsuta* (D.C.).
- XI. *P. viscosa* (Allioni).**—Syn., *P. hirsuta*—Villars, not Allioni = *P. graveolens* (Hegetschweiler) = *P. latifolia* (Lapeyr).
- XII. *P. hirsuta* (Allioni).**—Syn., *P. viscosa* (Will., and Godetr., non Allioni = *P. villosa* (Koch). Var., *P. Bernina* (Kerner)—*hirsuta* × *viscosa*. Syn., *P. graveolenti-viscosa* (Christ.).
- XIII. *P. cœnensis* (Thomas—Schott).**—Syn., *P. Daonenensis* (Leybold).
- XIV. *P. carniolica* (Jacquin).**
- XV. *P. spectabilis* (Tratinick).**—Syn., *P. Clusiana* (Tausch); *P. Polliniana* (Moretti); *P. integrifolia* (Pollini); *P. carniolica* (Pollini); *P. calycina* (Duby).
- XVI. *P. integrifolia* (L.)**—Syn., *P. Candolleana* (Reichenbach). Var. 1, *P. Muretiana* (Moritz)—*subintegrifolia* × *viscosa*; syn., *P. Florkeana* (Wegelin). Var. 2, *P. Dyniana* (Lagger)—*subintegrifolia* × *viscosa*.
- XVII. *P. Allioni* (Loiselenu).**—Syn., *P. glutinosa* (Allioni).
- XVIII. *P. glutinosa* (Wulfen).**—Var. 1, *P. salisburgensis* (Flörke)—*subglutinosa* × *minima*. Var. 2, *P. Flörkeana* (Schradner)—*subglutinosa* × *minima*. Var. 3, *P. biflora* (Huter)—*Flörkeana* × *minima*, or *minima* × *salisburgensis*. Var. 4, *P. Huteri* (Kerner)—*Flörkeana* × *glutinosa*, or *glutinosa* × *salisburgensis*.
- XIX. *P. minima* (L.)**—Var. 1, *P. Sturii* (Schott)—*minima* × *villosa*. Var. 2, *P. pamila* (K.)—*minima* × *cœnensis*. Var. 3, *P. intermedia* (Portenschlag)—*minima* × *Clusiana*; syn., *P. Flörkeana* (Salzer). Var. 4, *P. Facchinii* (Schott)—*minima* × *spectabilis*; syn., *P. Flörkeana* (Facchinii).
- XX. *P. Wulfeniana* (Schott).**—Var., *P. Venzoi* (Huter)—*Wulf. × tirol.* (Schott).
- XXI. *P. tirolensis* (Schott).**—Syn. *P. Allioni* (Koch).
- XXII. *P. marginata* (Curt.).**

The genus *Primula* is still so much in confusion that a monograph of it with good coloured drawings would be a great boon for botanical libraries. Nobody would be more competent to describe it than Prof. Kerner, of Innsbruck.

OTTO FORSTER.
Augsburg.

Chlorogalum Leichtlinii (Camassia siba) has just gone out of bloom in the open border, and appears to be perfectly hardy. It has stout, Tritoma-like leaves, and throws up a rather tall spike of pale, straw-coloured flowers, which look very pretty when expanded in the sunshine. When better known it will be grown in every good collection. Stems are very partial to its flower-stems.—H. HARPER CRAWES, *Drayton-Beauchamp Rectory, Tring.*

GREAT ST. BRUNO'S LILY.

(ANTHERICUM LILIASTRUM).

The order in which flowers are produced in the case of many plants is very singular. Nearly all species, the flowers of which are borne in indefinite spikes, as in those belonging to Agave, Delphinium, and Lupine, develop the lower blossoms first, the upper ones gradually expanding towards the top until the inflorescence is complete. In many of the tropical species of Angraecum, however, the reverse of this order is observable, for here the terminal flower on the spike opens first, and the one at the base last. Again, in Vanda Lowi, which bears numerous waxy flowers on a slender pendulous spike, the two first flowers, that is, those at the base of the spike, are coloured differently from the others, and they are fragrant, while all the others are scentless. In the tall yellow Asphodel, now everywhere in bloom, the flowers open promiscuously throughout the entire length of the spike. The large-flowered St. Bruno's Lily affords another example of singular floral development. Its pearly white, delicately perfumed flowers are normally borne on tall erect spikes; but, in addition, we recently saw plants each of which bore solitary blossoms, fully twice the usual size, at the base of the flower stem, and quite distinct from it, the flower-bud pushed through the soil on a little stem of its own. Our engraving shows a flower of this kind, exactly natural size, and in length of petal and general contour closely resembling some of the Pancreatiums.

B.

When visiting the Wellington Road Nurseries recently I noticed the following varieties of the St. Bruno's Lily, not hitherto known to me, viz., *A. Liliago majus*, the tallest-growing of them all, producing a long and fine spike of flowers, the petals of the individual blooms being tipped with green; *A. algeriense*, of much dwarfer habit, but with exactly similarly shaped flowers to those of the last-named variety, colour a pure white, without the green tips; *A. graminifolium*, with slender, Grass-like foliage, and the smallest flowers of all—indeed almost insignificant, save as a variety. There was also another variety just received from Algiers, named *A. bicolor*, which had not yet bloomed, and of the merits of which no account had been furnished. I there also learned the probable origin of the name of a so-called new variety of *Anthericum*, sent to me recently from the Continent under the name of *A. Reparni*, and which turns out to be simply *A. Liliago*, another designation of which variety is St. Bernard's Lily; this, in its Latin form, would be *Anthericum Bernardi*, and, if indistinctly written on a label, might easily be read *Rearni*.—W. E. G.

Your notice (p. 540) of the extraordinary peculiarity of St. Bruno's Lily in sending up large single flowers from the root, which open before the flowers on the spike, reminds me of the same thing in *Hemerocallis Fiddendorfaana*, but with a difference. In the *Hemerocallis* the flowers are produced in spring in the ordinary way on long foot-stalks, but in autumn other flowers are produced which are absolutely sessile. It is a very curious character in the plant for which it is hard to account, and which I have never seen noticed in any published description of the *Hemerocallis*.—H. N. ELLACOMBE.

The Double Yellow Rocket.—The double yellow Rocket (*Barbarea vulgaris fl.-pl.*) is one of the "old-fashioned plants" that one would again like to see in our borders now and then. The spikes of rich yellow are showy.—V.

ALPINE FLOWERS ON THE PYRENEES.

I AM in the realm of the Queen of Saxifrages, and a mighty region she has for a kingdom! thousands upon thousands of her silvery cushions stand the precipices as high as the eye can reach; some of them must be at least 18 in. in diameter, and have taken some years to arrive at a flowering condition. The ordinary cultivator of Saxifrages can form no idea of the splendour of this truly regal plant from the miserable specimens that are usually seen growing in pots in collections. *Ranunculus pyrenaica* is here in great numbers; I selected several varieties of it. There are thousands of acres of *Ranunculus Gouani*, *Globe-flower* (*Trollius*), various *Narcissi*, *Irises*, *Anthericums*, *Gentians*, and innumerable *Orechises*. I made two journeys from Luz to Gèdre, where I called upon M. Bordere, a schoolmaster, and a great lover of plants. He has a small factory in which he arranges and makes up herbariums, which he disposes of to visitors, and sends away to all parts of Europe. He has a collection of portraits of Englishmen, amongst which I saw those of Backhouse, Maw, Churchill, Packe, &c.; these he is proud to show visitors. From Gèdre to Gavarnie is one beautiful panorama of plants, among which are some of our finest Alpine flowers. Here I saw *Fritillaria pyrenaica* in the meadows, the white form of *Hyaclintus amethystinus*, sheets of *Androsace villosa*, *Saxifraga arctioides* by thousands, and *S. pyrenaica* innumerable; these two last grow together here; *Draba aizoides* is also abundant. Higher up I found *Saxifraga cæsia*, *Ranunculus Thora*, and the lovely *Cystopteris montana* in immense masses; *Gentiana verna*, *Primulas*, *Pinguicula grandiflora*, and *P. alpina*, abound everywhere where the earth is moist. I also saw *Ranunculus gramineus* at Gavarnie. At Barrèges I saw many acres of *Ranunculus pyrenaicus* growing on the hottest slopes, and in full flower; also *Pulmonaria cornuta*, a lovely plant, and by far the best of the *Pulmonarias*. *Daphne Cneorum*, *D. Mezereum*, and *Rhododendron ferrugineum* clothe some of the slopes. *Androsace carnea* is plentiful hereabouts, and what a grand plant *Adonis pyrenaica* is!

Hautes Pyrenées.

Abnormal bloom of St. Bruno's Lily.

Tyerman's Groundsel

(*Senecio pulcher*).—I obtained the seeds of this from a friend residing in Buenos Ayres, who collected them in the interior of the country, but did not name the exact locality. Six years ago I had but one solitary plant of it from a goodly packet of seed, and up to this time I have not succeeded in saving any seed. It is, however, readily increased by means of root-cuttings. In the "Botanical Magazine" it is said to be an annual, which is certainly not the case. On the contrary, I find it to be a free-growing, hardy perennial, growing about 2 ft. high, and flowering late in the autumn; indeed, I know of no more gay or interesting autumn-flowering, hardy border plant. It proves hardy with Mr. Nelson, near Norwich, who is charmed with it. I have given it to all botanical gardens and most of my friends. I may add that *Ixia*, *Sparaxis*, *Babianas*, and *Tritonias* are gay with me, though the weather has been much too dry and cold for the generality of Cape bulbs. *Lachenalia tricolor* and *Neris undulata* stood out with me and flowered as freely as under glass, although the past winter was unusually severe even for Cornwall, the thermometer on one occasion indicating 14° of frost. Bulbs properly so called were uninjured, but tuberous-rooted and semi-evergreens, half-hardy Cape and New World plants were much injured. Fruit crops, except Currants and Gooseberries, will be very light.—J. TYERMAN, Penlee, Tregoney.

THE INDOOR GARDEN.

THE GENUS CHYSIS.

This beautiful class of Orchids comes from Central America; they are all deciduous epiphytes, and have been frequently met with suspended from the larger branches of trees by their roots alone. The pseudo-bulbs, which, after the leaves have fallen off, remind one of those of a *Cyrtopodium*, are fleshy, spindle-shaped, pendulous, and often turning up at the tips; leaves arching, plicate, veined, and sheathing at the base; flower-spikes produced with the young growth, pendulous; flowers several on a spike. The different varieties of this genus resemble each other so much in the general characteristics of their growth and flower (except in the colour of the latter) that their proper specific names have been a matter of some discussion among botanists; for example, C. Linningshi was said to be a variety of *C. aurea*, and named *C. aurea v. maculata*; *C. bractescens* was said to be a variety of *C. aurea*, but it differs from that variety in several minor points, and more particularly in being furnished with cucullate, leafy bracts, which are wanting in *C. aurea*; *C. levis*, also referred to *C. aurea*, has the bracts as in *C. bractescens*. Whatever affinity they may bear to each other botanically they have been found under cultivation to be sufficiently distinct to warrant the preserving of their several distinctive names, and this course appears the more reasonable when we take into consideration the marked difference in the colour of their flowers. Blooming late in spring and early summer they make fine exhibition plants, and by judicious management they may be kept in beauty for a long time. All the varieties thrive best in baskets or pots suspended from the roof of the Orchid-house, the material used for growing them in being two-thirds fibry peat and the rest Sphagnum Moss and charcoal in lumps about the size of eggs. On throwing up their new growths, provided they be strong enough to flower, the plants should be but sparingly supplied with water until the flower-spikes are visible and are seen to be getting ahead of the growth, when water may be more freely given; after the flowering time they should be removed to a warm, moist, airy house until the pseudo-bulbs have attained their full size and the leaves begin to turn yellow, when water should be gradually withheld, and in a few days the plants removed to a cool house—about 55° by day and 50° at night—and kept dry for the winter; managed in this way they are amongst the most easily grown and free-flowering of Orchids. Occasionally some of the varieties of *Chysis* (particularly *C. aurea*) make a second growth and flower at the latter end of the summer; and, although this is detrimental to the plants in the long run, when it does occur the growth should be encouraged until completion in a warm house, and the plants should be afterwards rested in the ordinary way, when they may be again brought round to their usual time of flowering. Plants of *Chysis* when properly treated are not liable to the ravages of insects; the common thrips sometimes attack them, but they may easily be kept down by sponging the leaves with weak Tobacco-water. The plants are propagated by making an incision halfway through the running stem at the base of the back pseudo-bulbs when the leading growth starts; on the leading growth attaining a height of about 2 in., provided it does not show flower, the severance at the point where the incision was made may be completed, and the back pseudo-bulbs will soon start a new growth, when they may be removed to form a separate plant; should the leading growth show flower, the completion of the dividing had better be deferred until the plant has ceased flowering.

C. aurea.—This beautiful species was first found growing in the valley Cumacoa, in Venezuela, whence it was imported into this country in 1843, and was at that time the first and only one of the genus in cultivation. It has the same general appearance as the other varieties enumerated, the flowers, several on a spike, are from 2 in. to 3 in. in diameter, sepals and petals yellow, often spotted with orange, lip white and yellow streaked with crimson; it is rather capricious in its time of flowering, but blooms generally in May or June, and lasts about a fortnight.

C. bractescens.—A Mexican variety of great beauty, introduced by the late Mr. George Barker in 1840. The pseudo-bulbs are about 1 ft. in length; the flower-spikes bear each from four to eight flowers, each flower being from 2½ in. to 3 in. across, sepals and petals white, lip golden-yellow streaked with crimson. The flowers, which are wax-like and well-formed, remind one forcibly at first sight of a *Phalœnopsis grandiflora*, and hence it will be easily understood that the plant has great pretensions to beauty. It blooms in May and June, and lasts two or three weeks in beauty.

C. levis.—This beautiful variety appears to be nearly allied to *C. aurea*, from which it is distinguished by its longer flower-spikes, and by the middle lobe of the labellum being shorter than in that variety. It is a native of Guatemala, and has pseudo-bulbs from

A Ribbon Border early in June.—Our ribbon border is now in full beauty, and when bedding plants have just been put out, and scarcely yet become established, it is in beautiful condition. The front line, Golden Feather *Pyrethrum*, has assumed its golden tint; the next row, *Viola cornuta* Perfection, is thickly studded with flowers, and the third line is the pretty variegated *Dactylis*. The back ground for the border consists of a row of young plants of *Pinus Cembra*, which, being very dark green, exhibits the flowers in front of it to much advantage. Such a border as this may be had without any great cost or trouble. Another good border—a fit companion for that just described—may be arranged as follows:—In front put the delicate blue *Viola cornuta*, then *Iberis gibraltarica*, which produces such fine heads of white blossoms, and let the third row consist of the bright red double hardy *Pyrethrums*, than which there are no more beautiful plants at this season. As a back line for these a row of young bushes of *Retinospora plumosa aurea*, full of its fine golden buds, would be now most appropriate. There are many places in which a piece of bordering, such as I have mentioned, would be very interesting at this comparatively early season of the year, before the bedding out department becomes attractive.—R. McK.

Climbing Roses and their Uses.—What can be more beautiful (says Mr. William Paul, in the "Florist,") than an Ayrshire or Evergreen Rose scrambling up the stem of some old tree, which is probably bare of branches for the first 10 ft. or 12 ft. from the ground-line, although its lofty head is a fine feature on the outskirts of a lawn or shrubbery? Deftly and rapidly these Roses twine and wind themselves around the rugged trunk till they reach the branches above, where, spreading and bending downwards, the clusters of flowers gracefully intermingle with leaves and branches, moderating the glare of the skyward openings. Climbing Roses are equally well adapted for trailing over arcades, arbours, and rustic temples. For the purposes just indicated, the Ayrshire, Evergreen, and Multiflora Roses are the best. They grow vigorously when well fed, often making shoots 10 ft. to 12 ft. long in one season. They are very hardy, and, when fairly established, flower most abundantly. For low fences, the Hybrid China, the Hybrid Bourbon, and strongest-growing Hybrid Perpetuals may be used; and if a wall with a south aspect requires to be covered, whether high or low, some few of the Noisette, Tea-scented, and Banksian Roses are the very best kinds that can be planted. The general management of Climbing Roses is familiar to everybody. The Banksian Rose alone requires special treatment. It is common to hear of this Rose growing freely, but flowering sparingly. This is usually due to the system of pruning. Very little pruning is, in this case, necessary. The gross shoots should be stopped during the growing season, and the thin dry shoots removed early in the spring. The aim should be to obtain and preserve a goodly number of moderate-sized, well-ripened shoots, for it is such, and such only, that produce flowers.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Iris Daruis.—This is the name of a singularly beautiful and distinct variety of Iris, in the collection at the Exotic Nursery, Tooting. The uprights are yellow, and the falls netted with purplish markings, distinctly edged with yellow. It, like others of the family, may be compared, as regards beauty, to some beautiful and strange Orchid.—V.

Lathyrus Sibthorpi.—This is a beautiful early flowering Everlasting Pea, deserving of general culture. I raised my plants from seed obtained from Mr. Thompson, of Ipswich. It is not so strong in growth as the common Everlasting Pea, but it is a lovely border-flower, or for banks or the rougher parts of the rock garden.—U.

Pyrethrum aureum laciniatum.—This, which is being distributed by Messrs. Osborn, of the Fulham Nurseries, promises to be a desirable acquisition as a flower garden plant. It is a distinct, finely divided form of the popular Golden Feather, which is itself a variety of the common Evergreen. It is quite hardy, dwarf, and its delicately cut foliage has a very chaste appearance. This plant has received first-class certificates wherever it has been exhibited.

Woodruff and Ivy.—Having never elsewhere seen these two plants together, as I had for many years had them, a note on the subject may be useful. Banks and mounds clothed with common English Ivy are useful as boundaries, and to fill up angles and odd places. We have such a bank enclosing a playground, to which it forms a distinct boundary, while adding to it a peculiar charm. This bank was originally edged on the inner side with Woodruff, which has spread all over it, so that in the month of May, the new and brilliant growth of the Ivy, a mass of glistening green, is sprinkled all over with the white flowers of the Woodruff, which push through just enough to show themselves, as if they belonged to the Ivy, and there for three or four weeks they shine like a new snow-drover in the sun, and when they disappear there is not a chaffy stem or remnant to be seen. In another place we have a border filled with Hollies and surfaced with English Ivy, amidst which are planted yellow Crocuses and Woodruff. In March the Crocuses flower amongst the old leaves of the Ivy; in May the Woodruff flowers amongst the new leaves of the Ivy, and for the rest of the year the Ivy shines alone, a fitting ground-work to the shining Hollies above, and doing something towards making a garden in which there is not an inch of bare earth visible.—"Gardeners' Magazine."

12 in. to 15 in. in length, furnished with large, plicate, light green leaves; the flower-spikes are pendulous, bearing from six to nine flowers upon each; the flowers are fleshy; from 2½ in. to 3 in. across, sepals and petals yellow, stained at the tips with orange; lip, pale orange blotched with red; it is one of the most beautiful of its class, but, probably on account of its rarity, seldom met with in collections. It blooms in May and June, and lasts about three weeks in perfection.

C. Limminghi is a lovely variety from Guatemala, with pseudo-bulbs from 9 in. to 1 ft. in length, bearing lanceolate-acuminate leaves, about 6 in. in length, the plant having the same pendulous habit as all the other varieties; the flower-spikes, three of which are often produced from a single growth, bear each from four to six flowers, sepals and petals waxy-white, blotched or stained with lilac-rose towards the tips (more markedly in some varieties than in others); the labellum, as in the other *Chysis*, is three-lobed, the middle lobe, which is the largest, being pale lilac streaked with purple, and the two lateral lobes yellow streaked with crimson, the rich and clear markings of the lip showing to great advantage when contrasted with the delicate colour of the sepals and petals. It flowers in April and May, and lasts about three weeks.

C. undulata.—Under this name a very fine variety is to be met with, in a few collections, but whether the name be correct or not, I am unable to say. It appears to be a very fine form of *C. laevis*; the pseudo-bulbs are from 1 ft. to 1½ ft. in length; flowers, from six to twelve on a spike; sepals and petals, orange-yellow; lip, yellowish-white veined with rose. If it be a true species and be imported in quantity, and continue to bloom as well as the few specimens at present in this country, it will prove to be one of the best of the class.

C. Chelsoni is an interesting and handsome hybrid, raised by Mr. John Seden, at the establishment of Messrs. Veitch, of Chelsea. It was raised from seed of *C. Limminghi* crossed with *C. laevis*; the pseudo-bulbs resemble those of *C. bracteosus*; flowers, several on a spike; sepals and petals, nankeen; labellum, creamy white, with numerous rich violet-purple markings. It is a desirable kind, and well worthy of being placed by the side of the others of the genus; it flowers in May and June, and lasts about three weeks in perfection.

JAMES O'BRIEN.

STRIKING CUTTINGS IN WATER.

It is amusing to see (p. 572) a writer theorising on the advantages of water over soil and sand for striking cuttings, in the face of the fact that cuttings are struck by hundreds of thousands every year in sand and soil without any difficulty or appreciable loss. The water plan is an old and discarded practice that has been tried and found wanting, and which will, no doubt, be consigned to oblivion again as soon as some of your readers in search of novelty have satisfied themselves as to its merits (?). Thirteen years ago it was recommended and tried here, but only once. I found all the apparatus here when I came, which consisted of trays, &c., for holding the water and cuttings. For the sake of curiosity I tried a few hundred miscellaneous bedding plants, such as *Verbenas*, &c., in the water with due care, and lost 50 per cent. of them at least, while of those put into 5-in. pots at the rate of about 100 to a pot and plunged in a gentle hot-bed I hardly lost one. Those which did root in the water looked in the last stage of starvation, and were only saved by being transferred to their natural rooting media—soil and sand. It is seldom convenient and never advisable to pot cuttings off the moment they have struck root and are lifted out of heat, for they are too tender, and for this very practical and good reason cultivators place a layer of light rich soil below the top layer of sand, or they mix the two together, in order that the young plant may have a supply of proper food as soon as it forms roots; whereas by the water plan, unless they are waited upon attentively as they strike, they must adapt themselves to their aquatic circumstances in the best way they can. "The labour of draining and filling pots with compost," &c., and the "immense saving of labour and space" are not worth mentioning. I have for years in succession struck 50,000 cuttings of all descriptions between the end of February and the beginning of May in a three-light manure frame without losing more than 5 per cent., and I did not use above a few barrowfuls of soil, sand, and crocks for all. Cuttings could not be struck in less space in water than in soil, for we are in the habit of putting cuttings of *Verbenas*, and of similar plants in at the rate of 100 or more to a 5-in. pot—in fact, as thick as they will stick.

J. S.

Pot Roses for the London Market.—Mr. Philip Ladds, of Bexley Heath, has now several houses over 300 ft. long solely for the growth of Roses for the London market. *Niphetos*, *Isabella Sprunt*, and *Safrano*, are the sorts grown.

A NEW POT FOR ORCHIDS.

Our illustration represents a new form of pot for Orchids, samples of which were recently exhibited in London by Mr. Matthews, of Weston-super-Mare. Cultivators are well aware that epiphytal Orchids require but very little root-space when grown in pots; hence the pots have hitherto been partially filled with crocks (a snug harbour for cockroaches and woodlice) over which the compost has been placed. This plan answers tolerably well in practice, but the soil is often washed down among the drainage in watering, and the result is that the pot ultimately becomes clogged and the compost stagnant. In order to obviate this disadvantage Mr. Matthews has invented a pot for Orchids, of which the accompanying illustration is a section, and in which a circular earthenware disc is made to replace the mass of crocks that formerly were below the compost, the perfect drainage and aeration of which is secured without any danger from overwatering or the water

A New Pot for Orchids.

remaining stagnant in the compost. A circular disc with a hole in the centre is found amply sufficient, for all superfluous moisture readily passes away; but a lattice-work disc of earthenware can be substituted if thought preferable by individual growers. The new invention is simple, and has already been used with excellent results in many good collections. B.

BOUGAINVILLEAS AND THEIR CULTURE.

THESE rank amongst the very finest of stove plants, especially for covering a back wall or training on the roof, where, if the long drooping branches be allowed sufficient freedom, they have a charming effect. *B. glabra* is the freest-flowering of all the species; it blooms well even in a small state, and when it has room enough to attain a considerable size, it will keep in beauty during most of the summer. It is the best of the family for pot culture, either for the decoration of the stove or for exhibition purposes. Some account of the growth and flowers of this species will suffice as regards all the others. Bougainvilleas differ in many respects from all other cultivated plants, especially in the general appearance of the blooms; these are small and comparatively inconspicuous, not unlike the individual florets in a *Lantana*; they are associated with large bracts, which, when they are small and first appear, are green and almost the colour of the leaves; but, as they approach full size, about 1½ in. in length by 1 in. in breadth, they assume a beautiful mauve colour, and last, with little change, for weeks, the strong shoots producing a succession that keep on opening for a considerable time. As fresh growth is made, the flowering is prolonged with little interruption until autumn, especially when grown in a brisk heat. There is one peculiarity about *B. glabra*, that is, it will flower profusely in a cool intermediate house when planted out, but rarely makes much bloom when its roots are confined in a pot, unless it is grown in a high temperature. It also yields a much longer succession of flowers when in a warm situation

than in a comparatively cold one. The inflorescence of all the species are unequalled in a cut state for filling large vases, and they are equally suitable for bouquets, lasting longer with little or no moisture to support them than most flowers. They are all strong growers, and require a considerable amount of root-room to enable them to make growth sufficiently to show their true character; they will thrive in either peat or loam, yet the latter appears to suit them best.

I have already said that *B. glabra* is the most suitable for pot culture. It does not require a long rest in winter, consequently it may be started in the year. From plants so treated cuttings may generally be obtained by the beginning of March. These should be taken off with a heel as soon as they are 6 in. long, inserted singly in small pots with a little drainage, and filled with three parts fine loam to one of sand; they should be covered with a propagating glass, and placed in a night temperature of 70°, allowing it to rise 8° or 10° with sun-heat. Keep them moist and shade them from the sun, and they will root in a few weeks, when they may be moved into 6-in. or 7-in. pots, filled with loam mixed with one-fifth rotten-manure, and as much sand as will keep the soil sufficiently open to allow the water passing freely through it. After the plants get fairly established in the new soil they will need very little shade, but must have plenty of water, as when growing they will bear more moisture at the roots than most hard-wooded subjects. Syringe overhead in the afternoon, and raise the temperature 5°; by the middle of May pinch out the points to induce them to form several shoots; about midsummer they will, if all goes well, have filled their pots with roots, and should be moved into others, 10 in. or 12 in. in diameter, now using the soil in a more lumpy state than when the plants were smaller, adding a similar quantity of rotten manure and sand; place four or five sticks 4 ft. in height in the soil just inside the rims of the pots, round these train the shoots, tying them loosely, so as to give just the requisite support and keep them from getting entangled. Give air early in the daytime during spring and summer when the temperature of the house runs up to 80°; but close in the afternoons with the sun upon the glass, and continue to syringe overhead, and give plenty of water to the roots as soon as they have got well hold of the soil. This *Bougainvillea* is naturally so free in flowering that the plants will no doubt bloom in this stage of their growth; but, if the object be to grow them on to a large size, it will not be advisable to remove them when in flower to a conservatory, or similar cool house, so as to retard their progress. If, on the contrary, small-sized decorative plants be deemed the most desirable, they can be placed in a cooler situation during the summer months, but when used for such purposes this *Bougainvillea* requires to be treated in a way that few plants would bear.

When the flowers are about half grown, and before they have begun to colour much, the plants should be removed to the cooler house in which they are all to remain when in bloom; for if allowed to stay in strong heat until the flowers are fully matured, the check which they receive in that state generally causes them to fall off in a few days after they are placed in cooler quarters; whereas if they be moved as recommended above, whilst the flowers are growing, they will not only come to maturity, but last double the length of time—often five or six weeks—which they would in a high temperature, and the colour will also be many shades deeper. Yet it is not advisable to allow the plants to remain in too low a temperature too late in the season. By the middle of September at the furthest they should be returned to the stove, being likely to suffer if the night temperature of the house drop below 48°. When replaced in the stove, no more growth should be encouraged during the autumn, as there would be difficulty in getting it ripened up before winter. To prevent this, water should be withheld until the plants flag considerably, then giving only a little to freshen them up, but not so as to fully moisten the ball, gradually drying them off in this way until only enough moisture exists in the soil to prevent its becoming absolutely so dry as to endanger the roots perishing. This they will not do so long as even very little moisture remains, as before that takes place the leaves will have become ripe and have fallen off. Keep them in this state during the closing months of the year in a

night temperature of 55°, with 5° rise during the day. Where it is wished to extend the flowering as far as possible, they may be started early in January, raising the temperature 10° day and night, cutting out all the weakest shoots not strong enough to produce flowering wood; at the same time turning them out of the pots, removing any loose soil not occupied by roots, afterwards placing the ball in a pail of tepid water for eight or ten hours, so that it may get soaked right through, otherwise difficulty will be found in getting it properly moistened, without which the growth will be weak. After this immersion return the plants to the stove for a day to allow the soil to drain, and then put them in the pots in which they are to remain for the season. If they be not required much larger than the size they attained the previous year, they need not have pots above 2 in. larger than they have already occupied, using soil similar to that in which they have hitherto been, but with a little more manure in it. They should now be trained on wire trellises proportionate to the size to which they are intended to be grown. Syringe them every afternoon; in three weeks they will push young shoots, which will grow fast, and should, as they extend, be kept tied in an upright position; for, if allowed to hang down, it has the effect of stopping their free extension, inducing them to break back, and causing them to flower more sparingly by diverting the sap so as to prevent their getting so strong as may be desirable. As the roots begin to grow freely give plenty of water, for if over the young shoots, after they have made considerable progress, be allowed to flag through insufficiency of moisture, they will stop growing and set flowers, but in much fewer numbers than if the growth had been stronger before they were formed. By the middle of March, as the sun gets more powerful, raise the temperature 5° at night, allowing it to run up to 80° before giving air, and keeping the plants well up to the glass. *Bougainvilleas* do not require shading from the sun, the flowers coming higher-coloured when exposed to its full influence. About the beginning of April the plants should be in bloom, but at this early season they ought not to be removed to a cooler house. If the flower-shoots be trained down round the trellis, the plants will push up more growth, to assist which manure-water should be liberally given every other time they are watered; when showing flower, they can be placed in a cooler situation, and be thus prepared to stand a lower temperature when in bloom, after which they can again be further hardened off and wintered as before. If, instead of thus confining them in size, large specimens be wanted, at the spring potting, instead of placing them in smaller pots, they should have more root-room, giving them, say pots 18 in. in diameter, with larger trellises to train them on. Thus managed, they will last for several years, removing each spring about half the old soil, cutting back the roots proportionately at the time of re-potting, and supplying them liberally with manure-water during their season of active growth; at this stage of growth they will bear its application every other day.

B. glabra is equally suitable for planting out in either a hot stove or an intermediate house; when so used it should be grown in a pot the first season, not stopping the shoots until they have attained a length proportionate to the place which they are to occupy; the border in which it is planted should be well prepared by being efficiently drained, and should consist of 12 in. deep of good soil, similar in character to that recommended for pot culture. From the free-growing disposition of the plant, it quickly exhausts the soil, consequently as much should be removed each spring before growth commences as can be got away without too much interference with the roots, replacing it with new, at the same time cutting back the head of the plant as may be required, but in the growing season not keeping the branches too closely tied in, a loose free disposition of them being the most effective. When planted out it should not have much water in the winter.

B. spectabilis and *B. speciosa* are both more suitable for planting out than for pot culture, being stronger growers than the preceding. *B. spectabilis* succeeds better in the temperature of an intermediate house than when grown under warmer circumstances. The treatment which it requires is similar to that necessary for *B. glabra*, especially as regards a free use of the knife each spring, when it has got large enough

to fill the space allotted to it, always removing the weakest wood. The room allowed for the roots should in all cases be proportionate to the space which the head of the plant is intended to occupy, never giving too much soil, for being naturally a free-growing subject, it becomes difficult to keep it within bounds.

Bougainvilleas are subject to the attacks of aphides, thrips, and red spider. The two former may be destroyed by fumigation with Tobacco smoke, and the latter by a free use of the syringe. If scale or mealy bug affect them, the diligent use of the sponge and copious syringings must be resorted to, washing the plants, when cut back in the spring, with Abyssinian mixture (7 oz. to the gallon), or some other insecticide found to be effectual in destroying the pests. T. BAINES.

Calceolarias Damping off.—I have a collection of these in flower, but I am sorry to say that many of them droop and shrivel up when at their best. Could "Chef" (see p. 398) kindly help me out of the difficulty?—L. T. [Isolated cases of sudden drooping and shrivelling up of the foliage often take place among greenhouse Calceolarias. It is a disease akin to, or the same as, that which affects the bedding kinds out-of-doors. Among ordinarily well-managed plants it should not occur to a serious extent. In "L. T.'s" case the cause may be defective drainage, sour soil, or over-watering; but it is most likely brought on by sunstroke during the late fine weather. I would recommend your correspondent to shade the plants and pots from strong sunshine, to keep them regularly watered, but not sodden at the roots, and to sprinkle the floor of the house in hot weather, and preserve the air cool and refreshing; of course no fire-heat must be used.—CHEF.]

Selections of New Azaleas.—Many very fine seedling Azaleas were exhibited at the recent plant show in Brussels, and from amongst them we ("Florist") have selected the following, as the most desirable and novel in character.—M. Van Houtte exhibited Herman Lubbers, a large crimson, with dark purple spotting, and having a small, close petaloid tuft in the centre; and Professor E. Morren, a bright crimson scarlet, with several tiers of broad, smooth segments, forming a thin double flower; M. Jean Vervaene showed Flambeau, a very bright crimson, with small, oblong segments; Jean Vervaene, a very showy variety, with large, deep, salmon-coloured flowers, having a blotch of purple spots, and a flush of purple on the upper lobe, vermilion-red flakes scattered here and there, and a white margin formed of irregular patches running more or less inwards; Noble Belgique, very large, pale flesh colour, with purple spotting, and a broad white edge; and A. imbricata variegata, a double, with blush flowers flaked with red, the outer lobes being greenish. M. Joseph Vervaene showed a beautiful double-flowered variety named A. imbricata, as full as a good double Petunia, forming a close, solid flower; this is white, slightly barred and flaked, and of an entirely novel character. From M. Ch. Vuyksteke came Souvenir de Madame Rudolph Abel, a delicate blush white, with radiating patches of purplish spots on the upper segments, or sometimes continued also on the lower ones. M. E. Van der Cruyssen showed two Azaleas crossed with Rhododendrons, which retain the usual character in the flowers, except that they are very large. Of these Le Vengeur has the flowers of a bright, rosy pink, the edge slightly crisp, and the flowers fully 4 in. across; and Pucelle du Jardin is similar in character, with the flowers pure white.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Fancy Pelargoniums Grafted.—We are informed that the group of handsome Fancy Pelargoniums, shown by Mr. James, of Isleworth, at the recent South Kensington Show, were all worked on bottoms of the large flowering kinds. This is done when the stocks have several strong branches, and the result is found, not only in a more robust growth in the fancy kinds, but also greater longevity. The plants in question were about 3 ft. in diameter, perfect in form, and finely flowered.—"Gardener's Chronicle." [Mr. Henry Bailey, who, as many of our readers know, is an excellent grower of fancy Pelargoniums, informs us on the other hand that his fine plants were never grafted.—Ed.]

Varieties of Odontoglossum vexillarium.—Mr. Burbidge remarks in the "Floral Magazine" that scarcely two individual plants of this bear flowers exactly alike in either colour or shape. Messrs. Veitch have now several fine forms in flower, one of which is so soft and chaste in colouring that it fairly rivals all the others in delicate beauty. One of their specimens—a very vigorous one—bears ten strong flower-spikes, and Mr. David Thomson, of Drumlanrig, has a plant which has produced sixteen fine flowers from a single bulb. This noble species having recently been imported in quantity and in fine condition, we may soon hope to see it in every collection of Orchids.

CLIVEDEN IN 1876.

CLIVEDEN, the birthplace of spring gardening, well maintains the high character which it has so long and deservedly received for the beauty of its early flowers, its banks full of wild Hyacinths, Primroses, and Forget-me-nots, its closely-shaven lawns so overspread with wild Thyme that every footstep brushes up its fragrance, and above all its flower-beds brimful of spring beauty, now (June 17) just destroyed to give place to summer bedding plants. Looking from the terrace on the lawn, a huge sunken panel with flower-beds proportionate in size on either side of it, the floral display, when we saw it the other day, was magnificent. Brilliant pink, supplied by a large circle of *Silene pendula compacta* set in emerald green, was conspicuous in the distance; nearer were lavender and blue, furnished by *Nepeta corymbosa* and *Forget-me-nots*; buff, by *Limonanthus Douglasii*; golden yellow, by *Lasthenia californica*; and crimson, by the old China Rose of that colour and *Rhododendrons*; other colours, too, were equally striking, and these only a secondary display, that earlier and brighter being made by early Tulips. The plan is, when the Tulips are planted, to cover the surface of the beds with annuals, sown in July and August and transplanted when the bulbs are put in. These commence flowering when the Tulips are over, and remain in beauty until the bedding plants are planted out. Vasefuls of Tom Thumb Pelargoniums stand on the Grass near the walk at the base of the terrace wall, close to which is a ribbon border bright with Pansies, for which Cliveden is justly celebrated; and right and left are gardens of early flowers, arranged on the one hand in the form of a huge shell, and on the other in beds on the Grass that have been bright all the season, unfavourable though it has been, with spring flowers still in great beauty. But, brilliant as the floral display on the dressed ground undoubtedly has been, and soon will be again, it cannot arrest attention long. The eye is naturally carried beyond it to the woodclad hills and dales, the rich meadows, and the river Thames, at this season alive with water parties from Maidenhead and pleasure-boats of every description. These form the foreground, as it were, to a landscape unmatched for picturesque beauty, its distant boundary being the Surrey hills on the one hand, and the Chilterns, in Buckinghamshire, on the other. Vistas, too, have been cut here and there through the trees, so as to bring into view the water or some more distant object of interest. By reclaiming pieces of land here and there from the river, a wide and agreeable promenade has been formed along its banks, overhung at intervals by stately trees, consisting of Beech, Ash, and Elm, with here and there a Tulip tree and scarlet Chestnut. This is reached from the plateau above, on which the mansion stands, by means of winding walks and flights of rustic steps, through what may be termed a gigantic wild garden, consisting of ancient Yews, whose hold on mother earth is but small, their roots—weather-beaten and weird-looking—being half out of the ground; and tangled brushwood, fantastically overrun in places with Honeysuckle and Travellers' Joy. Here, too, even on the chalk, are masses of Ferns, and nearer the riverside a very fine Judas tree, clumps of Pampas Grass, mulberry-coloured Hazels, and other flowering and fine-leaved subjects, while in spring every open space is a garden of wild flowers.

Let us now return to the entrance front of the mansion. This we find has been strikingly improved, by removing the old kitchen garden and laying its site down in Grass as level as a bowling green, cut off from its surroundings right and left by newly-built walls, and in front by a Yew hedge, now old and much too thick, but still kept in tolerable vigour by means of good root treatment. These, with the mansion, enclose a spacious quadrangle, on the side of which furthest from the windows are large vases, that in early spring are gay with Tulips, and later in the season with annuals, the most effective of which is *Silene pendula compacta*, still masses of rosy blossoms. On the walls, which are covered with climbing and other wall plants, we remarked two Roses—single Persian kinds—one pale yellow, the other flame-coloured, both of which, to our mind, had a better appearance in such a situation than heavy double-flowered sorts. Honeysuckles and China Roses are also finely in flower here on walls; the former should never be pruned till they have done blooming. Else-

where we also noticed a Rose hedge, consisting of Fellenberg, a kind not very full when open, but excellent in the bud state for table decoration. Shut out from view of the mansion by the walls just alluded to, are the glasshouses, a conservatory being on one side and the forcing houses on the other—all now, and arranged with consummate skill and forethought as regards saving of labour; and the whole, with the exception of the conservatory, are built in parallel lines right and left of a central pathway, under which are the hotwater pipes, a glass-covered corridor running round the hot, and binding them, as it were, together. Close to them are the offices and young men's rooms, the latter built in a style and furnished with appliances such as are to be found in but few gardens. Grapes, Peaches, and other tender fruits are grown here in perfection, and among other things we noticed a houseful of tree or perpetual Carnations in flower, a brilliant sight—the blooms being abundant, large, and fragrant. Those who wish to have such flowers should put in cuttings now; but it will be found that old plants bloom best. Before leaving the forcing department, we should add that the extension system of Vine growing is that which is most in favour here, and that in one Vinery—an old one, 60 ft. long—one Vine has been allowed to fill the house. It is in excellent condition, and is now carrying some 200 bunches of promising fruit. Near here, too, is a glass corridor, the roof of which is covered with an aged Fuchsia of the corallina kind; several other varieties have been grafted on it, all of which are at present literally masses of flower and most effective, owing to the contrast produced by their different colours. Ivies, grown in zinc boxes and trained on trellises for indoor screens, we also saw out-of-doors here in the shade. These fit into ornamental trays, and when taken indoors have a Pelargonium, or Nasturtium, or some other flowering plant plunged in the box in front of them. The conservatory is 56 yards in length and 12 yards in width, and span-roofed, the spans being placed at right angles with the wall against which it is built. It is in two divisions, but so arranged that both can be thrown into one, which, when lighted up at night (which it is on certain occasions) has a fine effect. It is at present as gay as a house of the kind could well be.—Arum Lilies, as they are called, being especially good and conspicuous. Among the more arborescent vegetation which it contains may be named Oranges, carrying heavy crops of ripe fruit; and a vigorous specimen of Abutilon Boule de Neige, loaded with drooping white bell-shaped flowers, which, when inverted in bouquets with the stamens removed, have a charming effect. Against the back wall is *Lantana mutabilis*, quite a mass of variously coloured flowers, exhibiting, in fact, a luxuriance of blossom wholly unattainable by plants in pots. In the open air, just outside this house, was a beautiful example of *Chamærops Fortunei* coming into flower—a plant that, unprotected for five winters, has remained unharmed. Here, too, was a large specimen of the variegated leaved New Zealand Flax, equally hardy, the two guarding, as it were, the entrance to this in every way well-kept and handsome conservatory.

With the noble entrance to Cliveden, most people are familiar. It consists, it will be remembered, of a straight avenue of dimensions commensurate with the palatial residence to which it leads. This remains as it always has been; but the approach in connection with it has been greatly altered and improved. On the one side we have natural wood intermixed with flowering shrubs and trees; and on the other, here and there glades of Grass, pleasantly undulated and furnished with clumps of Rhododendrons and Azaleas—some near, some distant, but all effectively planted and more or less over-canopied with lofty trees, chiefly Beeches, whose stems rise for an unusual height clear of branches. A large stagnant pond, by which the road passes, has been drained, filled up, and converted into a Grassy lawn, one side of which hugs the approach for a considerable distance, while the other loses itself in the wood on the other side of the valley. Vistas, too, have been judiciously cut through the trees where the planting and views are most beautiful, thus rendering this portion of the grounds by no means the least interesting feature of Cliveden. Of the kitchen garden, now for the most part consigned to the farm, where it ought to be, we have said nothing, nor of the miles of green drives, in summer shady and pleasant,

with which the woods abound, nor of the indoor fruit-growing, which is excellent; but enough has been said to show that Cliveden, since it has become the property of the Duke of Westminster, has been greatly improved, both as regards its buildings and its gardens.

PLATE XXVI.

THE GENUS RAPHIOLEPIS.

(WITH A COLOURED FIGURE OF *R. SALICIFOLIA*.)

THE species of this small genus of evergreen shrubs inhabit China and Japan, and some of the adjacent islands. There is also in the herbarium at Kew an imperfect specimen of a shrub from the Sandwich Islands, which may possibly belong here. The Chinese and Japanese varieties fall into two very distinct species, the one, *R. indica*, having a loose inflorescence, as in *R. salicifolia*, the other, *R. japonica*, having a dense, close panicle of large flowers. Those belonging to the former need the shelter of a greenhouse in this country, whilst the latter are hardy in the south and west at least. The botanical position of the genus is next to *Photinia*, from which it differs technically in the calyx-lobes falling off early instead of remaining on the fruit; but more striking differences are furnished by the smaller leaves, and pyramidal inflorescence. The varieties in cultivation worth attention are:—

1. **The Willow-leaved *Raphiolepis* (*R. salicifolia*).**—This is one of the numerous varieties of *R. indica*, and by far the handsomest of any of them in cultivation, as a reference to *R. rubra* (Lindley's "Collectanea," t. 3) and *R. indica* (Bot. Reg., t. 468) will confirm; and the variety figured under the same name in the "Botanical Register," t. 652, is very inferior in beauty to our plant. Although the species to which this belongs bears the name of *R. indica*, it should be mentioned that it is found in no part of India. Some of the earlier botanists gave that appellation indiscriminately to plants from the West Indies, Africa, and Asia. *R. indica* is a native of Southern China, and is particularly abundant in the island of Hong-kong. It is an evergreen requiring the shelter of a greenhouse in this country, and a very desirable shrub for embellishing the conservatory in early spring. A detailed description would be superfluous here, as the accompanying figure shows all and more than one could describe. It is of slow growth and compact habit, the young shoots often overtopping the inflorescence, as represented in the figures quoted. Inferior varieties were in cultivation in this country very early in the present century, and the "Botanical Magazine" figure dates back to 1815. *R. Phœnestemon*, or Brown-stemmed *Raphiolepis*, is another variety, but it is of no special ornamental value.

2. **The Entire-leaved *Raphiolepis* (*R. integrerrima*),** Bot. Mag., t. 5510.—This species, or rather variety, for it appears to differ in no particular from *R. japonica*, except in having quite entire leaves, was first discovered by the officers of H.M.S. Blossom, between the years 1825 and 1829, in the Bonin Islands, and was published in the botany of the voyage (Beechey's) by Hooker and Arnott, in 1841. Subsequently the same form has been found in Japan, and even in the Korea. It is an evergreen of dwarf, compact habit, with stout, smooth branches, clothed with a light brown bark. The glossy obovate, or oblong leaves, are very thick and leathery, about 3 in. long by nearly two broad, and quite entire on the margin; and the fragrant white flowers are disposed in dense, terminal, bracteate panicles. In size, the flowers of this form are scarcely equal to some of the others, being only about three-quarters of an inch in diameter when fully expanded. From its native habitat this is probably the least hardy of the varieties of this species, but it is an exceedingly attractive shrub, and a great ornament to the conservatory or cool greenhouse. The date of its introduction into European gardens is unknown to me, but it seems to have been imported into this country from Continental gardens. According to the "Botanical Magazine," quoted above, it was first received at Kew from Berlin in 1862, and subsequently from several other places.

3. **The Toothed-leaved *Raphiolepis* (*R. ovata*),** Fl. Mag., 299.—Another form of *R. japonica*; indeed, this and the last together, with the intermediate varieties, may be said to constitute that species. It is a hardier shrub than *R. integrerrima*, from which it differs mainly in its minutely-toothed instead of entire leaves, and in its larger flowers, which are white and tinged with pink in the centre. As represented in the "Floral Magazine," the flowers exceed an inch in diameter, and the bracts of the inflorescence are

RAPHIOLEPIS SALICIFOLIA.

brown instead of being green and minutely fringed as in the foregoing. The flowers are succeeded by globular, glaucous, purple berries, resembling those of the Portugal Laurel. In a young state the branches, bracts, flower-stalks, and calyxes, as well as the under surface of the leaves, are clothed with a rusty tomentum. It forms a shrub or small tree, and is common in woods around Nagasaki, in Japan, and it sometimes grows in the clefts of rocks on the sea-coast. This fact would seem to indicate that it is a valuable shrub for the sea-coast in the south and west. At all events it is worth trying, for we have not a very large number of shrubs that will stand the sea-breeze and spray without suffering in appearance. Possibly, it may be as much at home in the vicinity of the sea as is the invaluable *Euonymus* from the same country. Moreover, it possesses the additional attraction of showy, agreeably-scented flowers. I believe this was introduced by the late Mr. J. G. Veitch, who regarded it as one of the most valuable hardy shrubs of recent introduction. It has been in cultivation in this country now upwards of a dozen years, but it does not appear to have become very widely known yet; probably, on account of its not being so easily propagated as the *Euonymuses* which have penetrated almost every garden in this country. The form figured in Siebold's "Flora Japonica" is almost identical with *R. ovata*, except that it has smaller leaves, and a somewhat loose panicle of smaller flowers. But this figure was most likely drawn from wild specimens. Siebold describes it as a shrub from 6 to 10 ft. high, growing chiefly in the southern provinces of Japan in the rocky places on the sea-shore and on the banks of rivers. This can only be regarded as really hardy in the south and west of Britain.

W. B. HEMSLEY.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Pot Roses.—Roses in pots, flowered in spring in the greenhouse without forcing, will now in most cases have finished blooming, and, where well managed, will have afforded a supply until Roses could be got out-of-doors. If properly cared for, such plants will keep on improving for many years. I have had both Hybrid Perpetuals and Teas in pots for eighteen years, and they were as strong and good at the end of that time as ever they were, although the pots used for them were not more, even up to the last, than 15 in. in diameter. The principal point to which attention must be directed is the encouragement of as much growth as possible through the summer, after they have done flowering; this can only be accomplished by keeping them thoroughly free from aphides and red spider, so as to preserve the foliage in a healthy state, and to never allow them to suffer from want of water. The pots should be plunged in ashes, where the plants will have plenty of sun and air, and growth should be assisted by a liberal use of manure-water. The shoots of plants used for spring flowering should not, after blooming, be cut back in the least; on the contrary, what pruning is required should all be done in winter, before they are put into the greenhouse; whatever they may need in the way of re-potting should also be done then. This kind of treatment is just the opposite of that which Roses should have that are wanted to furnish flowers through the last months of the year. These produce blooms on the ends of the shoots made through the summer, especially such kinds as Tea varieties, which are the best to use for the purpose. In the case of these the pruning and potting should be done after they have flowered, and every encouragement possible should be given to the summer growth.

Azaleas.—Plants of these that are making their growth should have plenty of water at the roots, and they should also be syringed freely. Wherever Azaleas are grown they will require to be narrowly watched for thrips, to the attacks of which they are very liable, and where they are in a house in which Vines are grown it is doubly necessary to keep them clear of thrips, or they are certain to get on the Vines, from which they are difficult to dislodge. As soon as the faintest trace of the insect is discovered, the plants should, if small, be dipped in Tobacco-water, but if too large to be treated in that way, the syringe should be used, taking care to wet the whole surface of every leaf, laying the plants down on their sides, over a vessel large enough to catch the liquid as it runs from them, and let them remain in that position until it has had time to dry on the leaves, which will make the dressing much more effectual. If set up before it has dried, it will run down into the soil, where it will be of no benefit to the roots. Tobacco-water may be obtained from the manufacturers, or it may be made by boiling for half-an-hour any of the preparations sold for purposes of fumigation, such as Tobacco cloth, paper, or cord, or pure Tobacco itself. If cloth, paper, or cord be used, an ounce to the gallon of common washing soda should be added: this will help to bring out the strength of the

material much more effectually than if nothing be used; if, in addition, two ounces of Gishurst Compound be put to the mixture this will counteract its oily character, and cause it to adhere more freely to the leaves. It is well to keep a supply of Tobacco-water in readiness, in which to dip or syringe any plant on which insects are discovered. By this means they may be kept in check with a fraction of the labour required when they are allowed to get to a head before means are taken for their destruction.

Camellias.—Plants that have flowered late which have not yet completed their growth should still be freely supplied with water, both at the roots and in the atmosphere, without which they will not make satisfactory progress. This applies to such as are in pots as well as those planted out. There are few plants for which a plentiful supply of moisture is more essential during their season of growth than Camellias; but should any be more than usually vigorous, and show an inclination to push a second growth rather than set flower, it will be advisable to allow the soil, for a week or two, to get drier than usual before giving water. This will induce a disposition to form buds rather than to make more wood. Camellias do not need so much pot-room as the generality of plants, especially if at all in a weakly state, but restriction in this respect must not be carried too far, or a stunted condition will be the result. Where larger pots are required, there is no time in the year when a shift can be so successfully given as immediately after the buds are formed, as at that early stage they are not so liable to drop as if moved later in the season when they have become larger. Camellias are frequently potted in spring after flowering, when growth is about to start or has already started; but any one who has had much to do with re-potting them must have noticed that the roots make very considerable progress before leaf growth has commenced, and that they are so extremely brittle that it is impossible to move them in spring without many of them being destroyed, and that at a time when a demand is about to be made upon them to supply materials for the formation of young shoots, which, in consequence, sometimes remain in a stunted state for years; whereas, if the potting be done as soon as the buds are formed, such checks are avoided. There is nothing that can be done to plants that have got into a stunted, naked state that will so soon and so effectually bring them round as planting them out in a bed of well-prepared soil, and where this is to be done there is no better time for carrying it out than as soon as the flower-buds are just formed, as the partial loosening of the roots from the compact mass into which they have been compressed in the pots they have occupied can then be done with less ill-effects than at other times. The bed ought to be drained sufficiently with refuse bricks broken about the size of pigeons' eggs, laid underneath the soil to a depth of 2 in., and some thin turves put on it to prevent the finer particles of soil getting down and obstructing a free passage of the water through it. Where strong, healthy specimens are to be turned out with a view to their remaining planted out, good fibrous loam is to be preferred, as in this they have not usually such a disposition to make so much growth as when in peat; mixtures of peat and loam I do not like. But for plants that are to be turned out for a time to recruit their strength good peat will be found the best, in all cases using enough sand to prevent the large amount of water which they require reducing the bed to a soddened, unhealthy state. To ensure success in planting out Camellias the following points require attention:—The ball of the plant should in all cases be sunk below the level of the bed, in order to allow for its settling, and the new material for some distance round the ball should at the time of planting be rammed as close and compact as the ball itself is left. When planted out they are less liable to get dry than when in pots or boxes, but when sufficient attention is not paid to planting them properly, I have seen them suffer from the effects of drought.

Flower Garden and Pleasure Ground.—More than usual attention should through the present season be paid to bedding plants, so as to get them to cover the ground, and flower freely without delay, or the long continued ungenial weather will have the effect of precluding the possibility of their making much display before cold weather sets in. Any blanks in the beds should be made up; mulching, pegging down, and watering when required, should also receive regular attention. Keep the Grass mown, so as to maintain a neat, orderly appearance; and all weeds, such as Dandelions and Plantains, should be cut out, or these will increase; the Plantain is much easier to destroy than the Dandelion, but tenacious of life as the latter is, if it be cut out persistently as it appears above ground, complete extirpation will be the result. Pinks, like other plants, are very late this year in making their growth; consequently the time for putting in pipings is later, but if this be not already done it should not longer be delayed. A large number may be struck under a hand-light in sandy soil, keeping them moist, close, and shaded from the sun, until they have become well rooted.

Stoves.

Achimenes and Gloxinias.—Most of these that were started moderately early will soon be in a sufficiently forward state for removal to decorate the conservatory, or to use in rooms in window recesses, a purpose for which they are well adapted, and where they last a long time in good condition, as the partial shade and comparatively still air of a room just suit their requirements while blooming. In removing them from the close, moist heat of the stove, they must gradually be inured to a cooler temperature before placing them in the conservatory or greenhouse, or the sudden transition will cause them to flag, and spoil any flowers already expanded, as well as those on the point of development. Make choice of positions where they can be kept somewhat closer than is desirable for the usual occupants of these structures, as a dry current of air coming in immediate contact with them will soon cut short their beauty. Later supplies of the above will now succeed best if brought gradually on in pits or frames, where they can be treated according to their requirements. Gloxinias have been so much improved of late that it is now the practice to get a packet of seed from which to raise plants, and to keep the best. Where it is desirable to increase any of these or other sterling varieties under name, leaves should be put in at once in order to afford time for good tubers to be formed before the autumn sets in. Make choice of those that are fully mature, and cut them off with an inch or so of the foot-stalk attached, after which insert in sandy soil, and place under handlights, arranged in shady positions in the stove or other warm house or pit, where they can be gently bedewed over to keep them fresh till rooted.

Rondeletia speciosa.—Among cool stove-flowering plants, few are more useful than the old *Rondeletia speciosa*, a plant that is not nearly so often met with as its merits deserve, for with a little management it may be made to bloom twice during the summer, and will stand for weeks during that season in the conservatory or greenhouse without suffering the least injury. Its beautiful bright trusses of flowers are almost equal to any of the *Bouvardias* now thought so much of, and to which they bear some resemblance. Young plants obtained now should be grown on in moist heat, and be well syringed to keep down insects, such as thrips and scale, to which they are subject. In potting, use good fibry loam, with a slight sprinkling of sand, to keep the soil open and porous. Any that are now showing bloom should be gradually hardened, preparatory to being removed to the greenhouse, where they are sure to be prized, and show to advantage among the commoner subjects usually there at this season.

Amaryllis.—These, like most other plants, have had their rise and fall in public favour, and, as is frequently the case with bulbs, seldom get that attention paid to them after flowering as to enable them to produce blossoms the following year. This may in part account for them going so much out of cultivation, for being so gorgeously beautiful, with fair treatment they ought to have held their own against all comers. So much is required in the way of flowers at most places, that plants, after blooming, get pushed aside to make way for others, and bulbs more especially come in for this hard usage, much to their detriment, for just at that time, of all others, they require the most care and attention to enable them to recoup their strength, form fresh flowers, and elaborate the requisite amount of sap to carry them through the period of rest. To assist them in this they must be well cared for now, by receiving the necessary renewal of soil, and being placed in position where they can get plenty of light, heat, and moisture; when grown with the general collection of stove plants, they rarely get sufficient of the former, to ripen and mature the bulbs, on account of the shade that has to be employed to suit the other occupants, and the distance they are placed from the glass. During the summer time there is no better or more suitable place for finishing these off than a common pit filled to within 18 in. or so of the glass with fermenting material, such as tan or leaves, that will afford a bottom-heat of from 80° to 90°, in which the pots should be plunged. This will induce them to form plenty of roots, and a corresponding amount of foliage, on which their blooming capacity depends, as the ripening process later on is a very simple matter, brought about by a full exposure to sun and air after growth is complete. In re-potting any that require it, remove as much of the old soil as possible without disturbing the roots too much, and replace it with good fibry loam, to which a little cow manure, that has been laid up for a year or two, may be added. Pots known as 32s and 24s are sufficiently large for the finest *Amaryllis*, as they do not require much root-room, and succeed best when somewhat confined, if properly supplied with water, when growth is most active. The slightest shade, just sufficient to keep the leaves from burning, is all they require after being placed fresh in the pit till they get over the effects of the shift and their new position, after which they will stand any amount of sun and be benefited

by exposure to its influence, provided they have air in proportion. Close early in the afternoon, and syringe heavily to keep the foliage clean and healthy, till the bulbs begin to ripen.

Hardy and Half-hardy Fernery.

Should the weather set in dry it will now be necessary to commence watering Ferns, or their fronds soon become disfigured by thrips and red spider, that are sure to attack them when there is a deficiency of moisture either in the air or at their roots. To hold these in check and keep the plants in a fresh condition as long as possible, they should be well damped overhead by using a syringe or garden-engine late in the afternoon, that the water may remain on them during the night. Where it can be used without being a disfigurement, a good heavy mulching of littersy material, or half-decomposed leaves, will be found of the greatest assistance, if placed a few inches thick, immediately around the stems of the plants, and as far as their roots feed. This will save much labour in watering, by intercepting evaporation, as far more moisture is lost in this way than the plants take out of the soil.

Stove and Greenhouse Ferns.—*Cheilanthes*, *Gymnogrammas*, and other farinose Ferns, if syringed at all, should only be very slightly bedewed, so that the mist-like moisture should fall lightly on the upper surface of the fronds; for, when applied in the ordinary way with any degree of force, the powdery deposit is knocked off, and much disfigurement caused. Most Ferns are now sufficiently advanced in growth to have the whole of the shabby, decaying fronds removed, but, in doing so, much care must be taken that the young tender growth does not become bruised or injured, which would spoil the appearance of the plants for the rest of the year. Any that are grown for general decorative purposes should be gradually inured to more air and a drier atmosphere as soon as the fronds have attained their full size, in order that they may harden and become stouter in texture so as to enable them to thrive in rooms or other positions in which they may be desired. Such Ferns as *Adiantums* and others that root freely must be kept abundantly supplied with water, especially if at all pot-bound, in which case they can scarcely have too much, and may be occasionally assisted with some weak liquid manure. Should green fly attack them—an insect to which they are very liable—while the growth is young and tender, the safest way is to dip the heads of the plants in Tobacco-water, as fumigation, however carefully done, is attended with much risk till the fronds become more hardened. Where an increase of *Gleichenias* is desired, the present is a good time to layer any of the rhizomes that have grown to a sufficient length from the pots they are in to be pegged down to some peaty soil in others placed near them. The rhizomes of most of the *Gleichenias* are of such a hard, wiry nature that it is difficult to get them to emit roots unless treated in this way, and to cut them about for purposes of division often entails loss. Most Ferns admit of increase so readily by division, that it only becomes necessary to adopt the slower process of raising plants from spores where large numbers are required, or of such kinds as cannot be manipulated in that way. *Lomaria gibba* is one of these, but as it comes so freely from spores, and soon gets to a useful size for furnishing, it is an easy matter to keep up a stock by annually sowing a few pots; this may be done at almost any time when ripe seed can be obtained, although, like most other subjects, they germinate best early in the spring. The pots should be prepared by being well drained with crocks to about a third of their depth, and then filled up with good turfy loam, pressed firmly down, with the top made perfectly level and smooth on which to sow the seeds: this should be done by brushing them off the backs of the fronds with a small brush, but in doing so they must be held close to the soil, or the air will carry them away on account of their minute size and extreme lightness. The soil should not come nearer the top of the pot than half-an-inch or so, to admit space for a piece of glass to be laid over without touching it; this must be kept constantly on till the seeds germinate, after which it may be tilted slightly for a time and then be removed altogether. To keep the soil in a regular state of moisture after sowing the seeds, the pots should be placed in shallow pans that must be constantly supplied with water till the plants show themselves, when it may be applied through a rose or syringe. A shady position, close under the back wall of the Fernery, or any warm house, will suit these Ferns, as long as they have sufficient light and the sun does not get at them to dry the surface of the soil. The above treatment, with more or less heat, according to the requirements of the variety, applies equally to all stove and greenhouse Ferns, and any from which seed can be obtained may be raised in that way. For table decoration and such like uses, *Lomaria gibba* is perhaps the most suitable of all, its symmetrical shape and Palm-like appearance rendering it well adapted for purposes of that kind. Several of the *Blechnums*, such as *B. brasiliense* and *B. corcovadense*, are

likewise valuable for the same purpose, and come freely from seed.—
—J. SHEPPARD, Woolverstone Park.

Orchids.

Shading will now require constant attention for if left down in dull weather, the leaves and pseudo-bulbs become unhealthy, and later in the season will exhibit disease; the blinds should not be let down too soon in the morning nor left down too late in the afternoon, for the plants in all the houses will be benefited by having the early and late sun on them, provided the ventilators be opened sufficiently to keep the temperature right. The ventilation, which requires great care, should be attended to as recommended last week (see p. 574); in order to ensure a free and equal circulation of air in both warm and cool Orchid-houses in summer, I have found it to be a good plan to lift up each of the lower lights of the roof where they rest on the gutter, with a chisel, and to place a piece of crook or wood about an eighth of an inch in thickness under each, leaving them there day and night until bad weather approaches. The little air that gets in through these narrow openings passes over the heads of the plants, but not near enough to injure them. I am convinced that fully one-half of the Orchids that die under cultivation do so from want of sufficient air. The cultivator must guard against excess of fire-heat during summer; there will be days probably on which it will be wanted, and it will frequently be good for the plants in the warmer houses at night, but it should be avoided as much as possible. At this season a temperature of 5° or 10° extra from sun-heat, provided the houses be properly shaded and a sufficiently moist atmosphere be maintained, will not be at all hurtful to the plants. All the varieties of Phalaenopsis will now be making new growth, and any of the plants requiring it should have the old Sphagnum carefully removed without injuring the roots, and its place supplied by Sphagnum in a living state. The plants should be suspended from the roof of the warmest house, and be freely supplied with water until October, care being taken not to sponge the very young and tender leaves of the Phalaenopsis, or when they come to maturity, they will probably exhibit scratches. The tender leaves of the growing Phalaenopsis are also very impatient of Tobacco fumigation.—JAMES O'BRIEN.

Roses.

Those intending to exhibit Roses will require to pay every attention at this season so as to protect the buds from the depredations of the various insects. May bugs are very destructive at this season of the year, the evening being the best time to destroy them; aphides should be thoroughly cleared off by means of the garden engine, and by carefully washing the trees the fly can be dispersed. It is not safe to apply any insecticide for the destruction of fly at this season, as the foliage and flowers are too far advanced, and if Tobacco-water or any other detergent be used and not efficiently washed off with clean water, it will often stain and spoil the appearance of the foliage. Tea Roses will be found to be attacked by mildew, owing to the cold and changeable weather; the best way to prevent such a mishap is to sulphur them carefully and then thoroughly to syringe the trees after three days. The caterpillar and Rose maggot should be picked off every day. The maggot will be found curled up in the foliage and in the centre of buds, and by steadily examining the Roses every day these pests may be well kept under. Take off all lateral buds, leaving nothing but the centre flower, so as to throw the strength into the single bud; by so doing the Rose is much larger and better formed. The buds selected for exhibition should be carefully staked and tied, so as to protect them from stormy weather, taking care not to injure the foliage in tying or supporting the young growth. Water the plants occasionally with a mixture of cow manure, sheep droppings, and soot-water, mixing the whole in a large tub, which will be found to improve the growth as well as the colour and size of the flowers. Such Tea Roses as *Marechal Niel*, &c., require a paper shade, where much exposed to the sun's rays, in order to keep the outside petals from being discoloured; by the use of paper shades Roses may be kept back a day or so, a delay which will be of great service to those who have but a limited stock to cut from. Roses when cut should be placed in tubes in water mixed with a small quantity of Condy's Fluid, to prevent them opening too quickly. Roses for exhibition should not be cut in full bloom, but should be about half expanded, the heat of the day very frequently being prejudicial to them.—H. G.

Hardy Fruits.

The general routine in this department now consists in destroying and preventing the spread of insects, and for a successful mode of carrying out this operation see previous recommendations, but it may be added that the utmost perseverance in the use of remedial measures is necessary to the extinction of the pests, as they increase with

startling rapidity when once they gain a lodgment, and especially when the weather is cold and ungenial. Remove the superfluous breastwood, pinch and tie or nail in the shoots required to be left for the furnishing of the walls, and finally, thin all kinds of fruits; this latter operation is not a formidable one this season, but still there are a few trees requiring to be thinned, for though the fruit crops are not such as was at one time expected, there are medium crops of all kinds, Apples excepted, and these are in this district a complete failure. The trees should receive the same attention as if they were full of fruit—a very necessary reminder, because of the disposition to neglect them when there appears no prospect of an immediate return. Cordons, bushes, and pyramidal-trained trees of Apples may now be pinched, that is, the new growths that are not required for the furnishing of the trees may be removed, in doing which well thin out all growths that intersect each other, the aim being to have light and air play about all parts of the trees. Cordons should be pinched in rather closely to keep the spurs as "close home" as possible, but judgment must be used in this operation, in order that growth be not too severely repressed at once. Of course, summer pruning or pinching of old orchard trees is quite out of the question; still, if this could be done, there is no doubt as to its being the proper course to pursue. The recent rains have been of incalculable benefit to the Strawberry crop, which will soon be ripening, and will therefore require protection from birds, mice, and rats—trap the two latter, and net over against the depredations of birds. It will soon be desirable to layer runners for next season's forcing, the best of which are always produced from plants that have been forced this season, and which were planted out a few weeks ago. There is also another advantage about this arrangement, viz., that as there is no fruit on them, injury is not caused to the runners by gathering the fruit, &c. Vicomtesse Héricart de Thury and President are the two kinds that have done best with us this year, and these two only will be forced next season. Each individual should find out the kinds which succeed best with him, and then grow those only. Cherries and Currants are now ripening fast, and must be protected with netting; in this district, birds are becoming so troublesome that netting is nearly useless, and the gun is the only effectual remedy, and which, in self-defence, we are compelled to use.—W. WILDSMITH, Heckfield.

CLERODENDRON KÄMPFERI FROM SEED.

This makes a stately plant, generally with one stem, which is furnished with broad, handsome leaves, and surmounted by a large and branching pyramidal panicle of scarlet flowers, that render it a most conspicuous object in the plant stove. It does best when raised from seed, which should be sown in summer or autumn, and the plants will flower the following season. A stove temperature is necessary for it from first to last. The seeds should be sown in light, rich soil, and the pot plunged in a bottom-heat of 85° or thereabout. When the seedlings are fairly up, and have one or two rough leaves, they should be potted off into 3-in. or 4-in. pots, in a compost of peat, loam, and sand, and a little thoroughly-rotten manure, and placed in a favourable position as regards light, but it is not necessary to plunge them after this stage. With heat and moisture they will grow away freely, and before winter sets in they should be shifted again into 5-in. or 6-in. pots rather than be allowed to get the least pot-bound. This shift will serve them till spring, and during the winter water must be given carefully—not too copiously—and they should be kept near the glass. About the end of February or beginning of March pot them again, and for the last time, in 10 in. or 12-in. pot, and use a good substantial compost, say, one part loam, one peat or leaf-mould, sand in sufficient quantities to keep the compost open and friable, and about one-fifth of rotten dung. Upon the getting up of a good vigorous stem and good foliage depends the size of the flower-spike and quality of the flowers. I like to see the plants come away with a good broad bottom. No pinching is allowable. When potted give them the highest stove temperature at command for the season, and afford them room and light, and water freely; keep the atmosphere around them moist, and adhere to this treatment till the flower-spike is fully developed. The plants will grow a good bit, and get large before showing flowers, unless they have been stunted at some time; but when the roots begin to fill the pot the spikes of flowers will appear and be thrown well up above the foliage. It is not very subject to insects; but if any bugs be seen among the buds pick them out carefully at an early stage with the point of the brush. To preserve the plants in flower as long as possible they may be removed to a cooler temperature. CHEF.

Alexander Peach.—Messrs. Silva and Sons, of California, excellent judges of Peaches, write to the "Gardeners' Monthly" that the Alexander ripens with them a fortnight earlier than Early Beatrice, and is one-third larger.

TREES AND SHRUBS.

THE WEeping SOPHORA JAPONICA.

ACCORDING to London the *Sophora japonica pendula* was first introduced into Europe by Father d'Incarville, who sent seedlings of it to Jussieu in 1747. It was first cultivated in England in 1763, at the Mile End Nursery, by Gordon, who probably received his specimens from Jussieu himself. The *Sophora*, of which the annexed are representations, is a fine specimen of this tree growing in the grounds belonging to M. Armand-Defresne, horticulturist, at Vitry, near Paris, and described by M. Carrière, in the "Revue Horticole" for May 16. Although there are many better and larger specimens of *Sophora* to be found, both in England and France, the tree growing in M. Armand-Defresne's ground is notable for its beauty and regularity of form, resembling, when fully covered with leaves, a series of cascades of foliage, gradually increasing in size from the top downwards. This tree is about 25 ft. high, the height of the stem being about 5 ft.; the circumference at the base is nearly 7 ft., and near the graft 5 ft. 6 in. Two facts relating to the flowering of the *Sophora* are somewhat remarkable, one is, that of late we hear much more frequently of its flowering than during the first seventy or eighty years after its introduction into Europe; the other, that only those portions of the tree which face the south, the east, or the west show any blossom. The tree also seems to begin to flower much sooner than formerly, a young specimen of it in M. Armand-Defresne's garden having shown several blossoms when only four years old. The causes of these phenomena we must leave to theoretical botanists to explain. The annexed woodcuts represent the winter and summer aspects of this tree, of which there are good specimens now in great beauty in the Fulham Nursery.

FINE CONIFERS.

By far the finest specimen of the *Wellingtonia gigantea* that has hitherto come under my notice I met with recently in the beautifully-laid out grounds of Kenfield Hall, near Canterbury, the residence of Mr. R. E. Toker-Thompson; its height, as far as I could guess, must be about 60 ft., and its outside measurement of branches, roughly measured by pacing round it, at least as many feet; and never before have I seen any specimen of this tree in such perfect condition or so beautifully feathered to the ground. It is well worthy being figured as a companion to the *Aracaria imbricata* at Dropmore. This *Wellingtonia* has been planted about nineteen years, and was 6 in. high when it came to Kenfield. In the same grounds are several fine specimens of *Aracaria imbricata*, producing a number of their curious cannon-ball-shaped-cones, which take nearly two years to come to perfection. The handsome long-spined *Pinus macrocarpa* (so seldom seen as a really fine specimen in this country, and which has not, I believe, yet coned in this country), is now showing its first cone on a fine specimen upwards of 70 ft. in height. This cone began to appear late in the autumn of last year, and being on the extreme top of the tree with only the young growth of this year above it, it is too far off to enable me to give any description of its form or shape. This species is said to produce by far the largest cones of any of the Pine family, some of those that have been imported weighing upwards of 5 lbs. The handsome and quick-growing *Pinus insignis* grew into a fine specimen in these grounds, but was killed during a not very severe winter two or three years ago, thus proving that this fine variety is not by any means so hardy as was expected. In California, in various parts of which it is found, it forms a fine tree, which often reaches a height of from 80 to 100 ft., and from 2 to 4 ft. in diameter, feathered to the ground with branches.

W. E. G.

Spanish Furze (*Hedy hispanica*).—This is unquestionably one of the most effective, hardy shrubs which we possess for lighting up, so to speak, our shrubby borders in spring, producing, as it does, at that season for weeks together dense masses of double bright orange blossoms in the greatest profusion. It is compact in growth, does not exceed 1 ft. in height, and is equally well adapted for front lines in borders, or for isolated tufts on Grass. It retains its foliage fresh and green throughout the season, and is in every way preferable to the common and better known double Furze, which soon becomes straggling and unsightly owing to its excessive freedom of growth, and it is consequently unsuited for any but semi-wild and rugged situations. The Spanish Furze, on the contrary, possesses so many good and desirable properties as to render it suitable either for small or large gardens. It is, in short, a very pretty shrub, which is worthy of being better known than it is, and more extensively grown. In St. John's Nursery, Worcester, are some famous examples of it—masses, a yard or more in diameter, having been established there for years.—GEO. WESTLAND.

The Evergreen Laburnum (*Piptanthus nepalensis*).—This is one of those plants which have been placed first in one genus, and then in another. Don names it *Thermopsis laburnifolia*; Wallich, *Anagyris indica*; Hooker, *Baptisia nepalensis*; and Sweet, *Piptanthus nepalensis*, a name now generally adopted, and one which is derived from *pipto*, to fall, and *anthos*, a flower—all the segments, stamens, and calyx soon falling off. The leaves are trifoliate and sub-evergreen, and the leaflets elliptic-oblong, acute, broad, and when young rather silky, but when fully matured, smooth, and deep green above, the decaying ones being yellow and green. The naked young wood is dark green and stout; the flowers are large, terminal, rich yellow at the base; the legumes or pods are broad-linear, compressed, six-seeded, and green, turning to brown when ripe in October. It forms an elegant sub-evergreen shrub, 8 ft. or 10 ft. high, which when clothed with beautiful, large golden flowers in May and June, makes a fine display. It is a native of Nepal, and is sufficiently hardy to withstand the winter in the open air in the neighbourhood of London, but further north it requires a wall.—G. G.

The Weeping Sophora (winter aspect).

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Hemlock Spruce in England.—The reason this Spruce does so indifferently in England, is, according to Mr. Meehan, probably the presence of limestone. The best soil for the Hemlock is that overlying granite. Even in America it does not thrive in limestone soils.

Trees on the Great Mountain Ranges.—On the Himalayas trees grow up to a height of 11,400 ft., and there are often forests just below this line. On the Andes the growth of trees ends at 12,150 ft.; on the Alps it ends on an average at 6,400 ft.; but it is stated that specimens of trees are found above 7000 ft. On the Himalayas there is no Grass vegetation above 15,400 ft., but the pasture-grounds in Tibet are known to extend over an elevation of from 15,000 to 16,300 ft.—"Statistical Reporter."

The American Mistletoe.—We have an American Mistletoe, which resembles the English species in leaf and manner of growth, although it is botanically quite a different plant. Its name is *Phoradendron flavescens*. It is found growing upon various kinds of trees in the Middle and Southern States. It may be propagated by grafting upon the wild Thorn Apple, Ash, Honey Locust, also the common Apple, and several other trees. The operation is performed by making an incision in the bark of the tree, and inserting into it a thin, wedge-shaped scion of the Mistletoe, having upon it a bud or two and at least one leaf. The best time for doing this is early in spring.

Berries for Birds.—I would urge the planting of Evergreens about the home grounds to afford shelter to the birds in winter. In addition to Trees and Shrubs for shelter, there are many kinds which produce fruit very acceptable to birds, although of no especial value to man, and these should not be overlooked in laying out and planting new grounds or improving old ones.—A. S. FULLER.

THE FRUIT GARDEN.

M. GLOEDE ON STRAWBERRY CULTURE.

CONTRARY to general opinion, M. Ferdinand Gloede maintains that Strawberries may be grown in any kind of soil, provided a certain amount of trouble be bestowed upon it, small enough when we consider the great benefit to be derived from the successful culture of this fruit. M. Gloede has seen Strawberries successfully cultivated in almost pure sand at Fontainebleau; but those who tried the experiment acknowledged that the results did not repay the attention bestowed on them. He also mentions having seen Strawberries grown in the back gardens of houses in large towns, in situations, however, which were well exposed to the sun and air, but in which there was, so to speak, no soil. The owner in this case, an enthusiastic experimenter, commenced by digging holes a foot in diameter and a foot deep, which he filled with a compost previously prepared, and in which he planted his Strawberries; every two years he renewed both compost and plants. In this way he managed for years to supply his table with excellent Strawberries. M. Gloede also mentions that he has seen excellent fruit grown on volcanic soil and common clay without the addition of any manure. He does not, however, recommend Strawberry growing under difficulties, and merely alludes to these facts to show that no soil, however poor in quality it may be, is wholly unsuitable for Strawberry culture. The chief point is to have the determination to succeed, and then all obstacles are easily surmounted. A Strawberry bed ought to be planted in an open and airy position, as far distant as possible from large trees, for strong sunshine, far from hurting the plants, is, on the contrary, favourable to them, provided the directions contained in the following pages be complied with. The ground in which the Strawberries are to be planted should be dug to the depth of at least 18 inches, and even deeper where practicable; where the ground is partly exhausted a good layer of half-rotten manure should be dug in. If the soil be heavy and damp horse manure, or fowl, rabbit, or sheep droppings should be used; if, on the other hand, it be light, cow or pig manure may be employed with advantage. If possible, this work should be done roughly before the winter sets in, in order to allow the frost to penetrate and pulverise the soil. If, on the contrary, the work have to be deferred until the spring or summer, the soil must be allowed to become firm before planting. If the soil be good and fresh, and not exhausted by other crops, manuring may be dispensed with for several years.

Time for Planting.

If convenient the grower had better commence to plant out early in July if possible, that is to say, if the young plants be sufficiently large to allow of their being transplanted. This method has two advantages:—the plants have time to get established before winter sets in, and are capable of yielding a full crop the following season; and there is no need to lose a

single plant, seeing that the operation can be carried on under the most favourable conditions both of time and weather. If the plants have to come from a distance, planting out ought to be delayed until September, as then they will not only travel with greater safety during the cooler weather, but they will be more vigorous, and will be provided with stronger roots, and will, consequently, take root again much more quickly. When the planting out, however, takes place so late in the season, so good a crop cannot be looked for as if it had taken place in July. September, however, is much the best month for general planting out, an operation which may often be deferred with advantage even till October. If, however, planting out cannot be finished before the end of October it would be better to wait until the spring. If planting out be done with the intention of gathering a small crop the same year, the operation must be begun early, say from the end of February to the end of March, according to the state of the weather. In

April the flower-buds begin to appear, and if transplantation takes place at that period the buds must be rigorously pinched off, for the plants will not have struck root with sufficient firmness to be able to bear fruit; besides, the ultimate success of the whole experiment would be compromised.

Method of Planting.

The ground having been prepared, the whole is levelled, and the beds or lines marked out. A hole of sufficient depth to receive the plant is carefully made with an ordinary garden trowel; the plant is inserted, taking care to properly spread out the roots, and the soil is then pressed round its neck or collar, which ought to be just level with the surface of the ground. In planting with a trowel, the roots are often pressed together into a mass in a perpendicular hole. This is a great mistake, and one productive of bad results, inasmuch as the young hair-like roots, which are so necessary to the future health of the plant, cannot develop themselves, and before new roots can grow from the neck of the plant it often perishes. The requisite number of plants having been planted, they are watered, even should the weather be wet,

in order to help the roots to fix themselves in the earth. In small gardens or plots of ground it is advisable to plant in beds or borders; but for cultivation on a large scale, where a few square yards of ground is of no consequence, the system of planting in rows should be adopted, for reasons to which I shall presently advert. A bed should measure at least 4 ft. wide, and should contain three rows of plants with equal spaces between them. When in rows the plants should stand quincunx fashion, a couple of feet apart. In borders a distance of 16 in. will be quite sufficient. These distances apply only to the larger sort; for the *Quatre Saisons* variety the bed may consist of four rows instead of three, the plants being from 12 in. to 14 in. apart every way. If it be desirable to make borders of the *Quatre Saisons* variety, the *Gaillon* kind is preferable to all others, inasmuch as it throws out no runners, and, as a matter of course, requires no attention in that respect.

The Weeping Sophora (summer aspect).

Treatment after Transplanting.

The most important point to which attention should be directed after the plants have become established is the regular nipping off of all runners at least once a week before they have even commenced to take root. The difference in the yield of a plant from which the runners have been regularly pinched off, and one which has been allowed to grow its own way and throw out as many runners as it liked, is incredible. The destruction of runners is a point which can hardly, indeed, be too much insisted upon, for not only is all the sap which goes to feed them absolutely necessary to maintain the mother plant in a state of healthy vigour, but the runners—trailing here, there, and everywhere—prevent proper attention being paid to the bed. When once the plants are in their proper places, all digging must cease, so as to avoid the danger of cutting off the fine fibrous roots which are thrown out from the necks of the plants in all directions to a great distance, and upon the free growth of which the health of the plants mainly depends. For keeping the ground clear of weeds, both rake and hoe should be constantly used. The plantations being made and attended to according to the preceding instructions, the plants will withstand the severest winter without protection. It is better not to remove the dead leaves as they wither, for they are useful in obviating the effects of severe frosts, and should only be removed at the end of February or the beginning of March.

Treatment before Fruiting.

As soon as severe weather is over, the dead leaves may be cleared away, and the soil lightly stirred with a hoe. It is as well to water the ground once a week with liquid manure, or in default of this, to spread over the surface a light layer of compost, consisting of half-rotted manure, wood ashes, or soot. The plants will now begin to grow rapidly, and as the end of March approaches, straw should be laid between the rows. For this operation neither Moss, fresh Grass, nor manure should be employed, the first two having the objectionable property of harbouring insects and creating mould, while the latter, if not entirely spent, would burn up the young leaves and hearts of the fruit. The straw prevents the fruit from becoming soiled, and it has the additional advantage of obviating the necessity for constant watering. Freshly cut straw should be used liberally, the whole of the ground being thickly strewn with it, care of course being taken not to cover up any leaves of the plants. Another material which is in high favour amongst growers is spent tan, which is said to be an effectual preventive of wire-worm. Besides the use of straw and tan, a handy little invention, called a *porte-fraise*, is sometimes used. The *porte-fraise* consists of a ring of galvanised iron wire, measuring about 6 in. across, provided with movable legs 12 in. in length. These are stuck into the ground in the middle of each plant. When the fruit is just beginning to form, the fruit-bearing stems are drawn carefully through the rings and allowed to hang over. Thus cradled, as it were, the fruit is more likely to ripen quickly than if it lay on the ground, and being exposed more fully to the sun, it colours more rapidly; on the other hand, rain does not do the fruit such serious damage as when it lies on straw or tan.

Gathering, Packing, and Transport.

The gathering of Strawberries is frequently done carelessly, and thus their handsome appearance is impaired. First of all, the fruit should never be gathered after nine o'clock in the morning, or at any rate before the dew has entirely disappeared. The stalk should be nipped with the forefinger and thumb, or cut with a pair of fine scissors a short distance below the calyx; the fruit, as it is gathered, should be laid in a flat basket and kept in a cold cellar or pantry until it is required. A Strawberry should never be washed, but if this operation be unavoidable from the strawing not having been properly attended to, it should be performed just before the fruit is set on the table. Strawberries which have a long distance to travel should be plucked with a pretty long stalk, and just before they have come to maturity, in order that they may have a better chance of standing the journey. Strawberries being so delicate are always more or less injured except when carried

by hand; shaking inevitably destroys the surface, thus rendering the fruit more liable to rot. For transport flat wooden boxes with tightly-fitting covers should be procured, the size of course being proportionate to the quantity of fruit to be carried, the depth being such as to allow room for only one layer of Strawberries along with their packing. A quantity of cotton wool should be laid on the bottom of the box and covered with fresh and dry Strawberry leaves. The fruit should then be laid in in rows, leaves being interposed between each row, and the whole should be covered over with a layer of leaves and cotton wool; the cover should then be put on and secured in any manner that is most convenient. A number of these boxes may be piled on each other and corded together. Thus packed Strawberries will bear a railway journey without damage. It is hardly necessary to speak of the excellent qualities of this delicious fruit, whether we look on it as a luxury or as a wholesome food. Unlike other fruit, it may be eaten without inconvenience at all hours of the day, and the old dictum that fruit is lead at night will not apply to the Strawberry.

Treatment after Gathering.

Many imagine that when once the crop is gathered Strawberry plants may be left to themselves for the best part of the year, until, in fact, the other portions of the garden have received attention. This is a mistake, for the plants, which are weakened and exhausted by having borne a heavy crop of fruit, need all possible care during the remainder of the fine weather if we wish to keep them for a second year with any chance of success. The first thing to do is to give the ground a good hoeing, and the plants a copious watering with liquid manure. Where the soil has been washed from the necks of the plants earthing up will be required, for it is from the neck or collar that the young rootlets, which are necessary to restore the exhausted plant to its former vigour, will spring. Weeds cannot be too carefully kept down, and after rains where the soil is heavy it must be stirred with the hoe or rake, copious watering being had recourse to in case of drought. It is scarcely necessary to repeat that all runners must be carefully pinched off before they strike root. Treated thus the plants will yield good crops for two or three consecutive years, although the fruit will not be so large or finely flavoured as if the biennial system of culture were adopted.

Biennial Culture in Lines.

M. Gloede strongly recommends this system of culture, especially for market purposes. After having dug and manured the ground lines are traced at a distance of about 5 ft. apart. This applies to the ordinary English-grown sorts, but not to the *Quatre Saisons* variety, which is best cultivated in beds. A dull or wet day in July should be chosen, and a number of young plants that were pricked out in June should be dug up with an ordinary garden trowel, a small portion of earth being left adhering to their roots. They are then removed to the prepared ground with every necessary precaution, and planted at a distance from each other of about 18 in. They should be well watered as soon as one line is complete, and so on until the whole is finished. Although the sun is very hot at this season of the year, shading will not be much needed. If they droop at all water them well thoroughly and often, and they will soon become healthy and strong. They will go through the winter without danger, and will yield a full crop of handsome and excellent fruit. It may be asked whether the spaces between the rows may be utilised, but most cultivators are agreed that it is better to leave them uncropped. The occupation of the intermediate spaces by other plants interferes with the proper culture of the Strawberries; and the soil which is to be occupied by a new row of plants the following year becomes exhausted and weakened. The crop being gathered, destroy the old plants, and plant fresh ones in lines between the old ones. Dig up the old rows, and manure well for the coming year. By thus alternating the rows year after year, excellent results will be obtained.

Culture on Elevated Rows.

It has long been known that Strawberries cultivated on raised rows ripen earlier, and yield fruit of a finer quality than when they are grown on flat ground, more especially in cold,

heavy soil. In this case M. Gloede recommends the following system, which, with the exception of the formation of the raised rows, is similar to that just described.—Trenches about a foot wide, and the same in depth, are dug at a distance of 5 ft. from each other, the bottom being filled to the depth of about 6 in. with half-spent manure, or half-rotten leaves well mixed together. The soil dug out is then replaced in such a way as to form a raised row or mound, after which the lines for the rows of plants are marked in the usual manner. When the soil has become sufficiently consolidated the planting is proceeded with, care being taken to follow the directions already given. When the planting is over, each plant is surrounded by four bricks almost entirely sunk in the soil. When spring arrives the mounds are covered with straw or tan, as already described in order to save the trouble of constant watering. Planted thus the roots of the young Strawberry plants keep perfectly healthy during the winter, and when hot weather arrives the brick enclosure and the strawing obviate the necessity of watering. This kind of Strawberry bed, when once made, has a neat appearance, and will yield extraordinary results.

Nursery Beds.

In order to have plenty of young healthy plants ready for forming new plantations, a portion of ground in a favourable situation should be set apart for the purpose. One or more beds may be devoted to this work, and the young plants should be pricked out in rows at suitable distances apart. Hoeing and raking should be constantly kept up, and all flowers should be diligently pinched off. Runners will also appear, and as soon as they begin to take root, they should be treated in the following manner:—Take a number of thumb pots, or "sixties," fill them with a compost consisting of equal parts of good mould and rotten manure, and bury them round each plant, one for each runner. Plunge the root of each runner into its proper pot, taking care to keep it in its place by means of a twig or peg; water well and daily, if necessary. At the end of a fortnight or three weeks, the pots will be full of roots, when the runners may be pinched off and the young plants left to shift for themselves. As soon as they have fully recovered themselves, they may be either transplanted to the place which they are ultimately to occupy, or, in case the necessary preparations have not been made, they may be turned out of their pots and plunged in mould, from whence they may be removed at any time. If intended for pot culture, they may be re-potted at once. If large numbers of young plants are required either for forcing or for planting in the open air, the rooted runners may be nipped off and planted at once, care being taken to perform the operation in rainy weather. They should be pricked out about 4 in. apart. These young plants will require a great deal of watching and frequent waterings during hot dry weather. The secondary runners thrown out by the potted plants should be pinched off as soon as they appear, as they tend to weaken the young plant.

Manuring.

It is essential that all the manure which is to be employed in a Strawberry plantation should be in a half-spent condition before being dug in. Pig and cow manure are specially fitted for hot and dry soils, which, indeed, will be benefited by almost any kind of manure; while horse, sheep, rabbit, and fowl droppings are better fitted for cold and heavy soils. The refuse from earth closets mixed with powdered wood charcoal also makes excellent manure; wood, turf, bone, coal ashes, and soot, are also of service. The surface of the ground should be sprinkled with one or other of them during the spring and autumn, advantage being taken of a rainy day for the purpose; guano mixed with water is also good, but if used in a state of powder it will burn up the young roots. Good leaf-mould, heath-mould, and garden-waste left in a heap and turned over now and then, are not to be despised.

Insects.

First comes the white grub of the cockchafer; which, if not checked in time, commits fearful havoc amongst Strawberry plants, especially in the case of light and dry soils. Unfortunately, it is only when it is too late that the presence of this

pest is perceived. A large number of remedies have been proposed for its destruction, but nearly all of them are useless. At one time it was proposed to plant Lettuces between the Strawberries, but the grubs seemed to show the same predilection for the roots of the Strawberry plants as before. Moles have also been encouraged, but they have only added to the cultivator's troubles, for their presence does not seem to diminish the numbers of the white worm. Ten or twelve years since M. Gloede tried four of sulphur with a certain amount of success. One square of his garden in particular was fearfully ravaged during the summer of 1863; he therefore determined to have the plot thoroughly dug up before the second year, in order to eradicate these troublesome visitors by hand, but unfortunately, on account of the drought, the work was put off till November, when the grubs had gone down to their winter quarters out of reach of spades and forks. The ground having been dug and manured, it was determined to replant it in the following February; before doing so, however he spread over one-half of the plot a thin layer of flour of sulphur, which was afterwards dug in with a fork; the other half was left in its original condition, and at the end of the month the whole square was planted with Strawberries. In April, when the grubs ascend to the surface, M. Gloede was agreeably surprised to find that the sulphured half remained untouched, whilst the rest was completely laid waste at the end of a fortnight. Whether the sulphur had really destroyed them, or whether they had only been driven into the unsulphured half of the ground remains to be proved. In this case, as in that of tan, repeated trials have proved that the sulphur will not always eradicate the pest; it is true that in certain localities the remedy has met with every possible success, whilst in others it has given a negative result, but as the operation is simple and inexpensive, it may be tried wherever the white worm makes its appearance. It is said that the sulphurous ashes from blast furnaces and ironworks are very effectual in destroying the grub of the cockchafer. Strawberry plants are also attacked by a small green caterpillar, especially early in the spring; it devours the young leaves with extreme rapidity, and ought to be looked for as soon as the gnawed leaves show its presence. A large grey caterpillar, with a very hard skin, and which is very difficult to discover on account of its colour, attacks the plants just below the surface of the soil; it is the same that so often attacks the collar of young lettuces and cabbages. Snails also do a great deal of damage, just as the fruit is attaining maturity, but is easy to get rid of them by placing here and there between the plants a number of small heaps of bran, a description of food of which they are exceedingly fond. Early in the morning, or late in the evening, they may be found congregated about the bran heaps, and may easily be picked off and destroyed. Ants attack the ripe fruit, and do much mischief; by placing in their way a number of saucers filled with honey, they may be collected together, and destroyed with hot water.

The Hautbois.

This variety, the English Hautbois, which was so justly esteemed by our forefathers, was almost exclusively cultivated before the introduction of varieties of American origin and growth. The cultivation of the Hautbois has been wrongly abandoned by cultivators, because, as they alleged, the species had degenerated and become barren, or else that the fruit did not please the eye, or that it possesses a peculiarly strong odour. The Hautbois is, however, to other Strawberries what the Muscatel is to other Grapes, and is certainly worth re-introducing into our Strawberry gardens. It is well known that among Hautbois there are plants of both sexes, some yielding flowers which are exclusively male, and others flowers which are just as exclusively female. There are also hermaphrodite flowers, of which there is no need to speak here. It often happens that in a large number of plants there are more males than females; the first year, however, the female plants yield an abundant crop. After the fruit has been gathered, the male plants, which are all the more vigorous from not having borne fruit, throw out an immense quantity of runners, which speedily cover the ground. The second year's crop is extremely small, the sterile male plants having completely invaded the whole plantation. The third year matters

become worse, and the plants are uprooted and their cultivation abandoned. The male plants should have all been uprooted the first year immediately after flowering, and only the hermaphrodite or female plants allowed to remain. Some growers imagine, but wrongly, that in order to have an abundance of good fruit on the female plants, it is necessary to plant male plants along with them, in order to fructify them, but the Hautbois, it must be remembered, will bear fruit—seedless, it is true—when grown alone. In a neglected plantation the fruit will, however, be pale and small, a circumstance which has tended to depreciate this variety. The Hautbois, more than any other sort, require a large amount of moisture. If the soil, therefore, be naturally dry, the plants will require copious watering, especially after flowering; they also dislike a warm situation, and thrive best when the plantation has a northern aspect; they likewise require less manure than the other varieties, being liable, if over-manured, to push forth leaves instead of fruit.

Propagation.

The Strawberry may be propagated in three different ways:—(1) By means of runners; (2) by division; (3) by seed. The propagation by runners has already been described. It is only necessary to add that in small gardens, where there is no space for the formation of a runner plantation, the number of young Strawberry plants necessary for renewing the old beds may be grown in the following manner:—As soon as the first "knots" on the runner are well developed, and before they have formed the tuft from which the rootlets spring, they should be cut off, trimmed, and planted in thumb-pots filled with good mould; they should then be removed to a northern aspect and covered with bell-glasses, and if they be shaded during the hottest part of the day, there will be rarely any occasion for watering them. The knots will soon throw out roots, and as soon as they begin to show at the sides of the pots the young plants should be gradually inured to the open air, and watered if necessary. At the end of a fortnight or three weeks they will be ready for planting in the open ground. Propagation by dividing the roots of the old plants is only adopted with one of the *Quatre Saisons* varieties, which throws out no runners; but in the case of rare varieties, which it is desirable to propagate as speedily and largely as possible, the practice may be had recourse to after the fruit has been gathered. The woody portion of the root is shortened, and the old leaves plucked off; the divided plants may then be planted in nursery beds in the open air. Rootlets will speedily develop themselves around the collar, when transplanting may take place. It should be observed that the larger varieties do not yield good results when propagated by root division, the plants being rarely so strong and fine as those grown from runners. As regards propagation by seed it is only the *Quatre Saisons* variety which exactly reproduces itself in that way, all the other large-fruited sorts, particularly those of American origin, varying greatly from the parent kinds, and rarely yielding the particular type sown. Recourse is therefore had to this method of propagation in order to procure new varieties. Strawberry seed rarely preserves its germinating powers beyond a year, and some growers, in order to make assurance doubly sure, sow as soon as the fruit is gathered, that is to say, in June or July. It is true that by this plan the seed germinates quickly, but the time before winter sets in is too short to allow the young plants to develop themselves sufficiently to resist the cold; it is necessary, therefore, to prick them in under glass and pay a large amount of attention to them without advancing their fruiting period by a single day. A much better plan is to clear the seeds from the pulp immediately after gathering and preserve in paper bags in a dry place until the end of February, before which period sowing should not take place.

Choice of Plants for Seed.

It has often happened that good varieties have been obtained by sowing seed taken haphazard from choice sorts, but races and types cannot be brought to perfection by chance. For the mother plant a sturdy fertile variety should be selected, the fruit of which leaves something to be desired in the way

of quality, and the pollen should be taken from kinds remarkable for fine flavour, if even they be not particularly large, and the habit of the plant not over-vigorous. At the end of February a number of earthenware pans should be filled with finely-powdered, but not sifted, peat-mould, mixed with a little powdered charcoal, some pieces of broken pots being placed in the bottom of the pans for drainage. The mould should be made tolerably firm in the pans, and watered, and the seed dusted over the surface as evenly as possible. It should then be pressed down lightly with the hand, and covered with a dusting of soot and powdered charcoal, a thin layer of finely-chopped dry Moss being spread over all, in order to favour germination, and prevent the seed from being disturbed by subsequent waterings. The pans should then be covered over with a piece of glass, and placed in a frame, the temperature of which is from 52° to 60°. The surface of the soil in the pans should never be allowed to become dry, and if the sun shine fiercely on the frame they should be shaded. In the course of a fortnight or three weeks, a full crop of young plants ought to have made its appearance. The Moss should now be carefully removed, and the young plants gradually inured to the open air. The greatest watchfulness must now be exercised in keeping out snails, for these unwelcome visitors may destroy the hopes of a whole month in a single night. In order to protect the young Strawberries more effectually, a dressing of fine soot may be added after each watering. As soon as the young plants develop their first pair of leaves, they should have more air, and when they begin to crowd each other inconveniently, they should be pricked off into thumb pots, after having pruned the roots somewhat so as to increase the quantity of fibres. For this purpose a good compost should be prepared, half ordinary mould and half old rotten manure, a small quantity of river sand and powdered charcoal being added. The thumb pots should be placed in a cold frame, which should be kept close for several days until the young plants have taken root. Air should then be gradually given them, and as soon as the fine weather has fairly set in, which generally happens about the beginning of May, they may be taken from the frames and placed in the open air. By this time they ought to be well grown, and may be transplanted to where they are intended to grow. They should receive the same care as plants grown from runners, the operation of destroying all runners being frequently and ruthlessly performed. By the beginning of winter they will have become strong and well established, and next year they ought to flower abundantly. They should now be frequently inspected, and those plants which promise to yield fruit of hopeful quality should be marked. A Strawberry plant, however, should never be judged by the fruit yielded by it during the first year, for it often happens that unsuspected qualities are developed during its second season of fructification, when the plants have attained their full development. Sowings of the *Quatre Saisons* variety should be made at the end of March in well-manured beds in the open air, and as soon as the young plants have formed leaves they should be transplanted into a nursery bed, and kept well watered and weeded. Six weeks or so afterwards they may be planted out, all plants being destroyed that do not flower the first year. [The opinions and practices of M. Gloede, who is one of the most famous cultivators of Strawberries on the Continent, cannot fail to be of interest to English growers. The above is translated for THE GARDEN from his excellent Essay on the Strawberry, published in French.]

Hardness and Rust in Strawberries.—This may, and often does, arise from drought. The plants may have been dried too much during their resting period, and their constitution impaired, or if after forcing begins, watering at any time be delayed till the leaves flag, the soft young rootlets that cluster round the sides of the pots are so far injured for the time being as to be unable to perform their proper functions, the plant receives a severe check, and deformed and inferior fruit is the result. I am of opinion that if Strawberries in pots are only once allowed to suffer from want of water, although water in abundance may afterwards be given, the check thus sustained will have a very deteriorating effect upon the crop of fruit.—E. HODDAX.

MELONS SPLITTING.

Most Melon growers have at times been annoyed by seeing their Melons, just as they were about getting ripe, cracking or splitting, and thereby not only completely spoiling their appearance, but, as often as otherwise, ruining them altogether. This splitting is said to be caused by too much moisture at the root, it being supposed that the rush of sap is too great for the fruit to withstand, and that it consequently bursts. This, however, I doubt. I have had crops that finished off well, and I have had others of the same variety that split badly, though both were grown under the same general treatment, and were ripened at the same period of the year. This season I have a long pit ripening off an excellent crop, without a single split in the fruit so far; and I have had neither a favourable season nor have I withheld water at the roots up till now, and the plants are green and growing, and look well for bearing another crop. These plants have been grown leisurely, with a moderate top and bottom heat, have never been damped more than once a day, and that slightly, and only on the afternoons of bright days; but they have always had plenty of air and water at the roots. Syringings have been given now and then, but a dry air overhead throughout has been aimed at. I should state that the plants are growing on a soil bed, and not trained to a trellis, and are, therefore, rather favourably circumstanced for splitting than otherwise. I never saw it occur badly, however, under such treatment. In a pit where splitting has been most troublesome with me I have not always complete control over the bottom-heat nor the moisture; and I have thought more than once that splitting has occurred when the ripening fruit was suddenly subjected to a higher temperature than ordinary, and perhaps a rather too close and moist atmosphere above. In the first case stated above the bottom-heat has been steady throughout, and rather low if anything. It is certain, as I can testify, that the fruit will crack and split nearly through in four-and-twenty hours; and this does not occur with one fruit only, but with all the same division that are that way inclined, which shows that it is the result of a general cause, and that this, it would appear, occurs suddenly, such as too much heat at the roots, and too much moisture overhead, when the former ought to be steady and the latter reduced to a minimum. Splitting from these causes may be produced under different circumstances—from the sudden application of heat supplied by hot-water pipes, or by a week of warm sunny weather after a period of cold, raising the heat of the bed too much. As regards Grapes, Peaches, Pines, Figs, Melons, or other fruits, my experience has impressed me with the fact that as the ripening period approaches a moderate and steady temperature is best and safest, whether size, weight, or flavour are considerations. All these qualities are sacrificed more or less by hurrying, and sudden jumps from a leisurely to an accelerated pace in the temperature—a course never advisable. With the Melon the pace cannot be too steady from the beginning, and should be adapted to the season of the year and the amount of daylight. The first and all-important consideration is to secure good foliage. Without this nothing can be done. Large leaves are a good sign if they have colour and substance; but these conditions cannot be secured unless the plants get time to grow, and have all the light and air possible, and then a crop of fruit is a certainty. I like to see a Melon leaf that cracks and breaks when crushed in the hand; a flabby, ill-constituted leaf only bends or folds up, and it is always upon these that red spider and thrips work destruction. A leaf firm in texture they can make nothing of, nor is splitting associated with such foliage, for it is not found under a high and irregular temperature, or a superabundance of moisture in the air. In Melon culture the syringe would, I cannot help thinking, be better laid aside. What possible advantage can it be to a plant which delights in dry sunny weather to be bathed in vapour twelve hours or more out of the twenty-four?—particularly seeing that it can be supplied with as much moisture as it wants, and more, through the roots. Circumstances arise in the culture of plants under glass which render it necessary to use moisture overhead in the form of dew; but a vapoury atmosphere I have always regarded as inimical to the welfare of most indoor fruits. I have known cultivators who, in order to sustain a constantly moist atmosphere in their Vineries and Melon-houses, &c., had a perforated lead pipe

taken along down the front pipes, so that the water dropped constantly upon them when hot, and so kept up a continual steam. For the same purpose, another laid his pipes in Sphagnum, which was kept saturated like a sponge. At all times the air in the houses was laden with moisture, unless the ventilation was so abundant as to let it escape. Good, though not well coloured Grapes were produced under this treatment, but not for long, for the Vines gave way. It is not casual crops, but the permanent health of the plants which affords the best proof of good culture. CHER.

Figs and Fig Culture under Glass.—Some Figs which I have under glass always ripen prematurely and imperfectly. What are the causes of this and of the rusty spots on the small Fig which I send? I have a good many Figs plunged in a border under glass, and though some always drop off very early, almost before they begin to swell, and others just before ripening, as shown by the larger specimen, this is the first time in which they have fallen as shown by the smaller sample. I believe that the roots are kept thoroughly wet—the subsoil is naturally dry; on the whole my Fig growing without heat is considered very successful. I have never quite succeeded in getting two crops in a forced house. [If Figs be planted out in the borders, with a great deal of room for their roots, and the soil rich, they produce very gross and succulent wood, and the fruit seldom ripens well. Figs under glass have always succeeded best with me in shallow circumscribed borders, top-dressing the surface with rotten manure, giving plenty of water at the roots during the growing season, and keeping them rather dry when at rest in the winter time. Figs grown in pots and tubs under glass are subject to the same routine, and are better not plunged in the soil, as they may root through the pots, and cause too great luxuriance, inducing the fruit to drop off before it begins to swell, or before the ripening period commences. As regards the small Fig sent with rusty spots, I believe that they are caused by a fungus of some kind, for on opening it, a mycelium may be seen spreading in the flesh, and rottenness setting in. Figs, when forced under glass with proper management, ought to bear two crops in a season. The first is generally not the best, for, under the best culture, many of the fruit drop off, owing, no doubt, to the sunless time of the year at which it appears if the trees be forced early. The second crop is always the most abundant if proper attention be paid to pinching the shoots in using surface-dressings of rich compost, and giving plenty of weak manure-water at intervals to the roots. The foliage should also be syringed once or twice a day, to keep red spider in check.—WILLIAM TILLERY, *Welbeck*].

The Golden Hamburg Grape in Pots.—Amongst Vines in Pots this has produced with me the heaviest crop, ever excelling in that respect the common Black Hamburg. Its berries are very large, and assume a beautiful rich golden colour as soon as they ripen—an important matter in the case of pot Vines. I see no reason why, if it had a fair trial for pot-work, it should not become extremely popular, as, like all Hamburgs on well-ripened canes, it shows fruit at nearly every eye, sets freely, and under the usual conditions swells up to a considerable heavier weight of fruit per rod than many of the varieties grown for supplying our earliest Grapes.—JAMES GROOM, *Henham*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Rust on Grapes.—I do not remember noticing that any one has attributed this to mere excess of heat: I do not mean steam or vapour from hot water pipes or fires, but an excess of temperature from sun or fire heat, or the two combined. I noticed a case that followed sharp on the heels of an accidental rise of temperature to about 95°. The Vinery had been shut up about two; the sun came out afterwards and no air was given; rust appeared two days afterwards. The Grapes were in about the middle of their first swelling.—D. T. F.

Double-sided Pots for Strawberries.—Pots are made, I believe, with double sides, to hold water, and these would possibly suit your correspondent. (see p. 584). If, however, he cannot procure them, let him place some cement at the bottom of a common flower-pot, of suitable size, keeping the hole clear, and whilst in a plastic state let him press another pot of a smaller size upon it, leaving about an inch space for water, or as much more as he may think fit: some makeshift of this kind may perhaps answer his purpose.—THOMAS GALL, *Leek*.

The "Fruit Mission."—Last December a "Fruit Mission" was organized by a number of ladies in this city (New York) who understood the needs of the sick in our public hospitals. The object is to supply fruit and other delicacies to the sick, under the direction of the hospital physicians. There are now between 3000 and 4000 patients in our public hospitals whose comfort would be increased and whose recovery would be facilitated by the use of fruit and delicacies not supplied by the hospital rations.

FLOWER SHOWS AND THEIR INFLUENCES.

It is the rule rather than the exception for flower shows to be got up as purely commercial speculations, and that by parties not interested in the least in horticulture. Prizes are offered for such productions as are likely to fill the exhibition tents most readily, and the very last thing thought of is the ultimate effect which such exhibition may have on the public taste, whereas if the funds were expended in rendering popular real improvements in horticulture some good might be the result. As at present constituted, however, flower shows are a dead letter as regards progress, for not only will the same plants and prize lists do for different societies, but they do equally well for the same society year after year. Is it to be wondered at, therefore, that exhibitions got up under such circumstances, lose interest? I firmly believe that, although the number of flower shows held throughout the country would lead one to suppose that exhibiting was popular, showing never was at a lower ebb than at present. Cultivators, as a rule, give full credit to their brethren who produce the finest subjects at exhibitions, of whatever class they may consist; but no one has the opportunity of knowing better than cultivators themselves that it is in the gardens under their charge that evidences of their ability must be found. In my way of thinking, growing for exhibition is distinct from gardening. There is in itself no harm in exhibiting; the evil is that such institutions as horticultural societies, founded with the best intentions, and in the hope of fostering horticulture, liberally subscribed to, should be made the very means of perpetuating the worst abuses of our gardens. In this neighbourhood at least one-third of the funds of each society is spent in prizes for cut Roses, both grown and staged in the most stiff, formal, and unnatural manner possible. No one can say that Rose-growing, properly so called, is stimulated by the outlay. The same may be said of other exhibition plants, which, if not trained in the orthodox fashion, stand little chance of receiving a prize. But cultivators do not grow what may be termed their decorative plants in this fashion; on the contrary, they dispense with staking and training as much as possible, and that to the advantage of both plants and growers. One consolation is that if cultivators of the present day lack interest in exhibitions as at present constituted, they are not behind their forefathers in all that really concerns the progress of horticulture.

Henham.

J. GROOM.

Town Gardens.—Thrift on a London window-sill.—I brought a very small tuft of wild Thrift from a mountain in the Snowdon region in North Wales, about four years ago, and planted it on my return to London in a Mignonette box at a bed-room window, in a north aspect, where it gets neither its bright mountain light nor its pure air, nor a single gleam of sunshine, at any time of the day, and yet it has survived four London winters with their smoke and smuts without injury—the Grass-like leaves shining healthy in their bright dark green, and each year throwing up flowers in profusion. It has become a fine large tuft, and has twenty-three flowers in full beauty at the present moment. I know of no other plant that would defy London smoke, and a dark north aspect, with anything like the same degree of hardihood.—H. N. H.

A Wall covered with Heliotrope.—I have frequently seen Heliotropes planted out in conservatories and other glass structures, but never so fine or so luxuriant as here. In a lean-to Vinery, 22 ft. long, the back wall, which is 12 ft. high, is a solid mass of it in perfect health. When I came here in March last, it was a sheet of bloom; it has continued so ever since, and I am told that it blooms continually nearly all the year round, producing an immense quantity of its fragrant blossoms, which are highly prized for mixing with brighter-coloured flowers in bouquets, or for table decoration. The more one cuts it, the more flowers it seems to produce, breaking out afresh below every incision. All the attention that it requires is an occasional soaking with liquid manure, syringing daily to keep down insects, and tying the young growths in as required to keep the wall well covered. It was planted by my predecessor, as near as I can make out about twenty years ago, and the amount of bloom which it has produced during that period has been marvellous. It is also very convenient early in spring to be able to gather cuttings by the thousand from which to raise plants for the flower garden, thus making autumn propagation entirely unnecessary.—H. HARRIS, *Denne Gardens, Horsham.*

M. MARÉ'S has recently calculated the amount of loss sustained by the Vine-growing industry in the south of France since the invasion by the Phylloxera. He states that 250,000 hectares of Vines have already been destroyed, giving place to other kinds of cultivation. This transformation has occasioned a harvest loss of more than 500,000,000*fr.* There are still in France 2,300,000 hectares the have not been affected.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

JUNE 21.

THIS, though an attractive exhibition, was not, on the whole, equal to the first summer show held here this season. Orchids were remarkably well represented, but stove and greenhouse plants were only of average merit, and among new plants there was nothing of any note which had not been exhibited before. Ferns and fine-foliaged plants were fairly well shown. Fruit, with the exception of Grapes and Queen Pines, was but sparingly represented. Mr. Douglas, however, had some excellent Strawberries, and Mr. Miles splendid Cherries, Figs, and Tomatoes.

Certificates.—These were awarded to the following new plants and florists' flowers:—

Rhopala pubescens (B. S. Williams).—A distinct and effective stove shrub, having pinnate foliage, which, when young, is covered with silvery hairs.

Rhododendron Princess Frederica (Veitch).—A greenhouse hybrid, having soft yellow flowers, relieved by crimson-coloured anthers. It is distinct in colour, and of free habit.

R. Prince George (Veitch).—Similar in habit to the last, but of a bright rose colour.

R. Prince Leopold (Veitch).—An orange-tinted variety, having a reddish throat. Like the two last-named kinds it bears its flowers in large trusses, and is well suited for pot culture.

Masdevallia Davisii (Veitch).—A clear, yellow-flowered Orchid, and one of the most distinct in the group to which it belongs, the flowers being an inch in diameter, and very freely produced.

Ixora regina (W. Bull).—A robust variety, bearing large trusses or orange flowers, and furnished with glossy green foliage. For general decorative purposes, or for exhibition, it well deserves culture.

Hibiscus Colleri (W. Bull).—A distinct flowering plant, having glossy green foliage, and bearing axillary double flowers, of a soft salmon colour, the bases of the petals being streaked with crimson. The individual flowers are rather fugitive, but as they open in quick succession, the plant remains attractive for several weeks. It is a native of the South Sea Islands.

Smilax Shuttleworthii (W. Bull).—A strong-habited stove climber, having dark, glossy, green foliage, marbled with dull, silvery-grey. It will be useful either as a pot plant, or for covering pillars or back walls in warm plant houses, where its leaf beauty can be seen to advantage.

Maranta Massengiana (W. Bull).—This plant is very distinct, having horizontal, roundish, oblong leaves, of a deep, velvety, green colour, traversed by grey lines. It is one of the most effective of all new Marantas, and deserves careful culture as a stove decorative plant.

Aralia splendidissima (W. Bull).—A large-habited, pinnate-leaved plant, which has previously been certificated and described in our columns.

A. spectabilis (W. Bull).—Another variety of more elegant habit, and a welcome addition to a well-known and graceful group of stove plants.

Artocarpus Cannoni (W. Bull).—A dark-leaved stove plant, previously described.

Croton Mortei (W. Bull).—A strong-growing variety; having broadly oblong leaves, profusely veined and mottled with gold.

Dracæna insignis (W. Bull).—A dwarf and compact plant, well suited for table decoration. Its leaves, which are lance-shaped, are dark purple margined with crimson, and the whole plant is scarcely 15 in. in height.

Dieffenbachia Shuttleworthii (W. Bull).—An oblong-leaved plant of a clear glaucous green colour, the mid-rib being marbled with silvery-grey. It has been previously certificated.

Dactylis glomerata latifolia aurea (E. G. Henderson).—A broad-leaved variety of the common "Cocksfoot" Grass, the recurved leaves being profusely striped with creamy yellow. It promises to be a first-class plant for edgings, or for other decorative purposes, when grown in small pots.

Pelargonium, Wallace (Rev. J. Matthews).—A crimson scarlet show variety, irregularly veined, the upper petals being of a dark velvety-purple tint. It is a distinct and useful addition to what are termed show kinds.

Pelargonium, H. S. Ryder (Rev. J. Matthews).—A rosy pink show variety, the upper petals of which are spotted with black. The flowers are large and smooth, and have a conspicuous white eye.

Pelargonium, Bridesmaid (Foster).—A rosy-purple show flower of good form and substance, the upper petals having a dark maroon spots.

Pelargonium, Purity (Foster).—A soft salmon-red show variety, having dark upper petals. The plant is of good habit.

Pelargonium, Charming (Burley).—A cerise scarlet Zonal of good habit, the flower being composed of well-rounded smooth petals of a distinct tint.

Perlargonium, Mrs. J. O. Quennell (Burley).—A variegated Zonal, of compact habit, having bright silvery-edged foliage and pink flowers, the latter very freely produced; as a pot plant or for bedding purposes it is a decided acquisition.

Fuchsia Laing's Hybrid (J. Laing).—A very distinct hybrid Fuchsia, raised from *F. fulgens* and crossed with one of the more modern florists' varieties. It possesses a vigorous branching habit, and bears bright reddish, long-tubed flowers, the corollas of which are of a brighter red or rather carmine. As a decorative plant it deserves general culture.

Lobelia corulea albo-marmorata fl.-pl. (W. Bull).—This is a double blue variety marbled with white, and one which may not inaptly be described as a double-flowered *L. Paxtoni*. It is distinct and pretty, either for out-door beds or for pot culture.

Perlargonium, Sappho (Turner).—This is of such a robust and free-blooming habit that it is likely to be largely grown for market purposes. Its flowers are of good form, the colour being brilliant rosy-carmine with a black spot on the upper petals, these colours appearing all the more distinct on account of their being contrasted with a pure white eye.

Orchids.—These were shown in better condition than we have hitherto seen them this season, and being arranged on sloping turf banks were seen to the best advantage. Among the more recent specimens we noted well-grown plants of *Saccolabium guttatum*, the pale-rosy *Odontoglossum vexillarium*, *Arides odoratum*, and *Masdevallia Harryana*, from Mr. Heims; Mr. Salter had well-flowered plants of the orange-scarlet *Epidendrum vitellinum majus*; also *Odontoglossum Alexandræ*, *O. Pescatorei*, and *O. citrosomum roseum*, together with *Laelia purpurata*, and an exceptionally fine *Oncidium macranthum*, bearing over fifty great yellow and brown flowers. Mr. Denny, who furnished one of the best groups of twelve plants which we have seen this year, had *Cattleya Wardii* in splendid condition, one plant bearing eight carmine purple-lipped flowers, and also a fine *Cattleya Mossii*; in this group was also a remarkable variety of *Oncidium Lanceanum*, bearing a great branched spike of brown, mottled flowers, having a great purple lip; *Anguloa Clowesi*, *Cattleya Leopoldi*, and *Dendrobium Bensoniæ*, were also represented by well-grown specimens. Mr. Ward contributed an effective collection, in which there were well-bloomed examples of *Odontoglossum Blunii*, the white *Dendrobium formosum*, a good potful of the Bearded Lady's Slipper, and well-grown plants of *Odontoglossum vexillarium*. Mr. J. Douglas had a fine variety of *Cattleya rigida*, with delicate rosy-petalled, purple-lipped flowers, and also a fine variety of *Masdevallia Harryana*. In the nurseryman's class Mr. B. S. Williams had a large example of *Cattleya Mossii*, bearing twenty-one flowers; also the Bearded Cypripedium, the purple-spiked *Orchis foliosa*, from Madeira, with twenty-five flower-heads, and good plants of *Arides affine* and *Odontoglossum citrosomum roseum*. The same exhibitor likewise furnished *Cypripedium superbiens*, bearing ten fine flowers, a good potful of the orange-scarlet *Epidendrum vitellinum*, *Brassia aurantiaca*, *Anguloa*, and *Lælia*. Messrs. Jackson, of Kingston, had *Cattleya Mossii* with deep rosy purple-lipped flowers and other well-grown species.

Stove and Greenhouse Plants.—Of these the best twelve specimens came from Mr. J. Ward, gardener to F. Wilkins, Esq., of Leyton, among whose plants were wonderfully fine examples of *Xora amboynensis*, bearing considerably over 100 trusses of soft orange blossoms; *Kalanthes Phœnix*, 4 ft. in diameter, and a mass of fragrant scarlet flowers; *Clerodendron Balfourianum*, 5 ft. high, and 3 ft. in diameter, and a mass of fresh green leaves and rich scarlet and white flowers. Two of the most effective plants in this group, however, were the purple-lilac *Statisia profusa*, 5 ft. in diameter, and *Bougainvillea glabra*, a mass of delicate mauve-purple and green, 5 ft. high, and nearly as much through—a really splendid specimen. Associated with these were likewise *Brioa tricolor* and *E. Essensei*, with tubular varieties, both well grown and well flowered. Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, had also an attractive group, his best specimens being *Dipladenia amabilis*, with bright rosy, salver-shaped flowers; *Bougainvillea glabra*, *Xora Fraseri*, *Chorozema Chandleri*, the Jasmine-like *Rhynchospermum*, and a good plant of *Balfour's Clerodendron*. In the nurserymen's class, Mr. B. S. Williams and Messrs. Jackson and Sons both had well-grown collections; Messrs. Jackson contributed *Allamanda grandiflora*, with pure yellow, salver-shaped flowers; a good *Pilea mirabilis*; a well-grown specimen of the nearly white and deliciously fragrant *Stephanotis floribunda*, and the scarlet-spotted *Anthurium*; Mr. Williams' best plant was *Xora Prince of Wales*, a garden hybrid, with nearly yellow flowers, bright and effective, especially when contrasted with the blue *Statisia profusa*, or other purple-flowered plants; the same exhibitor had also a splendid plant of *Stephanotis floribunda*, and *Arides odoratum*, bearing nearly thirty flower-spikes. Of Ferns and other fine-foliaged plants there were several good collections.

Perlargoniums.—These were well represented, the best nine large-flowered or show varieties being those sent by Mr. J. Ward; the varieties were *Confagration* (scarlet with black spots), *Maid of Honour* (rosy-salmon with maroon spots), *Example* (rosy-carmine with black spots), *Princess of Carmarthen* (rosy spots and white eye), *Royal Albert* (salmon with maroon spots), *Caractacus* (purple with white eye), *Princess of Wales* (rosy lilac with dark spots), *Pompey* (vermillion, upper petals maroon), and *Emperor* (rosy-flesh with maroon blotch). The above were shown, and trained plants, each of which measured from 4 ft. to 6 ft. in diameter, and well deserved the premier prize which was awarded to them. The best six fancy varieties came from Mr. G. King, gardener to R. Tew, Esq.,

Essex; these consisted of well-grown shield-shaped or sub-globose plants, measuring from 2 ft. to 4 ft. in diameter, and perfect masses of bloom. The varieties were *Princess of Teak* (white with rosy spots), *Formosum* (rose and white), *Tormentor* (maroon and rose), *Mrs. Alfred Wigan* (deep rose with white eye), *Roi des Fantaisies* (white with rosy upper petals), and *Madame Saintron Dolby*, similar to the last but much smaller. The same exhibitor was also first for six show Perlargoniums, the varieties being *Hermit* (white with rosy blotch), *Filomena* (carmine with black blotch), *Desdemona* (white with red blotch), *Exhibitor* (carmine with maroon blotch), *Beauty of Kingston* (white with dark purple blotch), and *Rival* (soft salmon, inclining to vermillion, blotched with red). Scarlet and Zonal varieties were well represented, the best being those sent by Mr. King. His varieties were *Delightful* (soft pale salmon), *Clipper* (vivid scarlet), *Gloire de Corbey* (salmon-scarlet), *Leonidas* (vivid scarlet), *Mrs. W. Paul* (delicate rose), and *La Grande* (crimson-scarlet nosegay). These were shield-shaped plants, measuring from 5 ft. to 6 ft. in diameter.

Miscellaneous Plants.—These were very tastefully arranged in groups in the centre of the large tent, a position in which they made an effective display. Messrs. Veitch & Sons contributed a choice group, in which we noted a yellowish-coloured variety of *Oncidium crispum* named *flava* with flowers similar to those of *O. Marshallianum* in shape and size, but of a soft greenish-yellow colour, and, in addition, excellent specimens of *Phyllanthus roseus pictus*, *Arctocarpus laciniatus metallicus*, *Adiantum princeps* (one of the freshest-looking and most effective of all Maiden-hair Ferns), and several beautiful new hybrid greenhouse *Rhododendrons* and *Begonias* of the tuberous-rooted section. In this group we also noted the new *Sarracenia* named *Stevensi*, a kind with greenish pitchers similar to those of *flava*; the yellow-blossomed *Masdevallia Daviesii*, and an exceptionally fine plant of *Veitchii*, bearing four splendid flowers. In the same group was also a fresh-leaved example of *Hemathus cinabarinus*, bearing a dense, globose head of vivid orange-scarlet flowers, and the more sombre and graceful beauty of choice Ferns, Palms, Crotons, and *Dracenas*, was further enlivened by several stands of pink, white, and creamy *Peonies*, *Iris*, and *Stocks*, and a strong plant of the scendant yellow-flowered glaucous-leaved *Tropæolum polyphyllum*. Mr. W. Bull furnished a choice group of new and rare fine-foliaged plants, several of which obtained first-class certificates. Messrs. E. G. Henderson and Sons had a fine bank of hybrid herbaceous *Calceolarias*, margined with lines of Zonal *Tricolor Perlargonium* *Peter Grieve*, and the creamy variegated *Dactylis glomerata latifolia aurea*, one of the most graceful of all variegated Grasses. Behind these was a choice collection of *Beaucarneas*, *Palms*, *Arads*, and *Dracenas*, and examples of the new and extremely graceful *Prenanthes elegantissima*. Mr. B. S. Williams showed a large and choice group of new and rare plants in excellent condition. In addition to *Orchids*, *Amaryllids*, *Crotons*, *Dracenas*, and other flowering foliage plants, we remarked *Hyacinth maculata*, glossy bronze-coloured foliage; *Blandfordia grandiflora*, with pentagon orange-golden-rimmed flowers; and several choice *Sarracenas* and *Begonias*. Mr. R. Parker contributed one of the most attractive groups of hardy plants we have yet seen exhibited; it consisted of lemon, yellow, sulphur, crimson, and white *Peonies*, blue and white *Bellflowers*, white and rosy *Pyrethrums*, and some well-selected blooms of *Bearded* and *English Irises*, a pale blue-flowered *English Iris*, having a yellowish-white lip, being especially beautiful; with these were well-arranged *Maiden-hair* and other hardy, slender-leaved *Dracenas*, various *Hyacinth maculata*, *Hardy-tongue*, and other British Ferns. Messrs. Paul, of Cheshunt, sent several large basketsful of cut *Roses*; Mr. Charles Turner had beautiful blooms of *Miss Hassard*, a rosy flesh-coloured kind, and also examples of the *Rev. J. B. Camm*. Mr. Oshard also sent several stands of *Roses*; and Mr. Roberts, of Peterborough House, Fulham, and Mr. Wheeler had groups of cut flowers of hardy plants; blooms of *Catherine Bell*, a new climbing *Rose*, of which we gave a coloured plate some time ago, came from Messrs. Bell & Son, of Norwich. It is a bright rosy variety, with silvery-lilac backs to the petals, and is said to be one of the most beautiful of all pillar and trellis *Roses*.

Fruit.—Black Grapes were fairly well shown, the best being some clusters of *Black Hamburg* from Mr. W. Nash, gardener to the Duke of Beaufort at Badminton, and Mr. Okehurst, gardener to G. Gage, Esq., of the Grove, Highgate. Heavier Grapes than these were shown, but not so well finished. Mr. Douglas sent three fine clusters of *Royal Ascot*, a large-berried black Grape, likely to become a favourite; Mr. Grimmet had three large-berried bunches of *Madresfield Court* in good condition. 12-lb. baskets of *Black Hamburgs* came from eight exhibitors, but those that were best finished came from Mr. Okehurst; Mr. Kay also showed a good basket. *Muscats* of *Alexandria*, small in berry, but otherwise in excellent condition, came from Mr. Robbins; Mr. Grimmet was second with clean, large, well-berried bunches; Mr. Douglas had good fruit of the *Cannon Hall* variety. Good clusters of *Foster's Seedling* were shown, but they were green; good 12-lb. baskets of *Muscats* came from Mr. Grimmet and Mr. Kay; and Mr. Atkins sent a good basket of *Buckland's Sweetwater*. Scarcely ripe *Melons* were poorly represented. Mr. Wildsmith, of Heckfield, being first with *Hero of Bath* (scarlet-fleshed), and *Heckfield* (green-fleshed); Mr. Ward also had a prize for *Longford Castle* (green-fleshed), and *Longford Castle* (scarlet-fleshed); Mr. Miles, of Chertsey, had a fine fruit of *Golden Perfection*; Mr. Miles, of Chertsey, had *Elton's* and *Black Circassian*, were as near perfection as possible. Mr. Douglas had the best *Strawberries*, the varieties being *Duc de Magenta*, and *Seedling No. 1*, of his own raising. The same exhibitor had excellent dishes of brown *Turkey Figs*. Mr. Woodbridge

Ston House, showed a dish of well-grown Vanilla pods, large and fragrant. From Mr. Miles came three boxes of Tomatoes, viz., Carter's Green Gage, a globular fruit resembling yellow Plums Stamfordian, and Large Red, all in excellent condition. Mr. Douglas also had three fine dishes, among which the Green Gage variety was very fine. Of Peaches, which were poorly represented, there were five dishes, and of Nectarines six dishes, the latter good fruit, consisting of Violet Hative, Elruge Brugeon, and Scarlet. Of Queen Pines, some excellent fruits were shown by Mr. Ward, gardener to G. N. Nutter, Esq., Bishop's Stortford.

ROYAL HORTICULTURAL SOCIETY.

JUNE 21.

This meeting taking place, as it did, on the day on which the Royal Botanic Society held its great show, was but a small one. The Rev. M. J. Berkeley gave an account of some Morello Cherry trees in his garden which produce flowers of three kinds freely. In one set there was not the slightest trace of any stigma; an intermediate set had a short and abortive pistil, while a third set consisted of a few normal flowers, which produced, however, but a small proportion of fruit.

First-class Certificates.—These were awarded to the following new and rare plants:—

Mormodes luxatum eburneum (Sir T. Lawrence).—A strong-growing Orchid, having fusiform pseudo-bulbs 5 in. or 6 in. in length and glaucous, lance-shaped leaves; the flowers, which are large, are borne fourteen to sixteen together on a stout, arching spike, 15 in. or 16 in. long, and are of a milk-white colour and slightly fragrant; the column, which is stout, is curiously contoured (as in *Goodyera*), an arrangement evidently intended to facilitate cross-fertilisation by means of insect agency. The plant, as exhibited, is very beautiful, and well worthy of careful culture.

Azalea indica imbricata (Veitch).—A double-flowered variety of a greenish-white colour, flaked with carmine, the flowers being freely produced even on very small plants. At first sight the blossoms remind one of those of a double-flowered *Petunia*. It is the most perfectly double of all the so-called Double Azaleas, and is likely to prove a useful decorative plant.

Miscellaneous Plants.—Sir Trevor Lawrence showed a small group of Orchids in excellent health, and among them we noted a very dark purple-spotted variety of *Odontoglossum Roezli*, named *atro-purpureum*, bearing nine flowers, and two species of *Mormodes*, namely *M. pardinum*, with golden-yellow flowers on a second spike, and *M. luxatum* var. *eburneum*, which has creamy-white blossoms. To a remarkably well-grown plant of the hybrid *Calanthe Dominyi*, bearing eight fine spikes of purple flowers, a cultural commendation was awarded. The Rev. J. T. Boscawen, Lamorran, Probus, Cornwall, sent a very large and beautiful variety of *Iris Xiphoides*, bearing blue flowers. Several effective blue and purple-flowered bedding Violas were furnished by Mr. R. Nash, of The Household, near Gerard's Cross, Bucks. Mr. C. Lidgard, Albion Road, Hammersmith, sent a basketful of blue and lilac bedding *Lobelias*, of the *L. pumila* section, and a scarlet Zonal Pelargonium of good habit, and some large and beautiful seedling Forsythes came from Mr. Warren, gardener to the Earl of Portsmouth, Hurstbourne Park, Hants; Messrs. Cripps & Sons, of Tunbridge Wells, showed a dark purple *Clematis* named *Othello*, said to be a seedling from *C. viticella venosa*, to which it is superior in both colour and form. With it came a seedling *Begonia* (*C. Pearcei* crossed with *C. Sedeni*) which has the foliage of the first-named kind coupled with soft orange-yellow flowers. Mr. Miles, of West Brighton Nurseries, Cliftonville, sent a new *Mignonette*, which bears very long spikes of white fragrant flowers. Col. Trevor Clarke contributed a hybrid Pink raised from a purple flake *Carnation* crossed by a purple Indian Pink. It is of robust and free-flowering habit, the colour of the semi-double flowers being brilliant carmine. A well-grown plant of *Dianthus multiflorus* came from the Society's garden at Chiswick, together with a variety named Lord Lyons, which is one of the best of the decorative kinds. Mr. Osman, gardener to the South Metropolitan District Schools, sent a small and interesting collection of Zonal Pelargoniums; and from Mr. J. B. Goubert, nurseryman, of Kilburn,

came a rosy salmon-flowered *Carnation*, of tall habit, named *Madame Goubert*, which promises to be useful for cutting. Mr. Dean sent out flowers of *Petunias* and *Nasturtiums*, and a very showy stand of purple, white, and rosy Canterbury Bells (*Campanula Medium*); from Messrs. Waite, Burnell, Huggins, and Co., came a dwarf variety of *Saponaria calabrica*. A plant of the pink-flowered Zonal Pelargonium *Cleopatra* was shown from the Society's gardens at Chiswick; it has scarlet flowers, and the normal ones are pink; this kind was raised from a variety called *Cerise*, which was itself obtained from a dull scarlet variety, and in the plant exhibited, the production of the dull scarlet flowers shows a case of reversion to two generations, and was very interesting, as throwing some additional light on the phenomenon known as bud variation.

City of London Flower Show.—The report of the committee for the past year has just been issued, from which it appears that the annual exhibition of plants and flowers, held in the gardens of Finsbury Circus in July last, proved a great success, exceeding all its predecessors both in the number of plants exhibited, and in their mode of culture—many of them being, in the opinion of the judges, remarkable examples of successful cultivation. Several special prizes were given by gentlemen interested in the matter. The Rev. F. Bishop is the honorary secretary, and all communications should be addressed to him at the schools, Bishopsgate. The residents of Finsbury Circus have granted the use of their gardens for the flower show to be held next July, and it is expected that the Duchess of Teck will distribute the prizes.

NOTES AND QUESTIONS—VARIOUS.

Transplanting *Lilium giganteum*.—This Lily will bear moving even after it has made considerable growth. We moved a large plant of it here after it had four flower-spikes over 2 ft. high without its sustaining the least damage. A good watering after planting was all the attention which was given to it, and now after a month in its new quarters it is thoroughly established.—H. M.

Geranium *Robertianum album*.—This is a pure white-flowered form of the Herb Robert, and one of the prettiest of all wild Geraniums. Some vigorous tufts of it have established themselves on the moist walls of a large tank in Messrs. Rolleston's Nursery, at Tooting, where they are now flowering profusely, each individual flower standing out clear and bright as a silver star. Planted in moist and shady parts of the rock or root garden this plant would be perfectly at home, and it would also prove a good addition to the wild garden.—B.

Lilium Thompsonianum (*Fritillaria macrophylla*) has been in beautiful bloom in the open border here for a week. It has stood the winter well with a slight covering of Cocoa refuse. It reminds one much more of an Antherium than either a *Lilium* or a *Fritillaria* in its general growth; but, of course, its bulbous roots point to the two latter genera. Its pale rose-coloured flowers are excessively pretty, and it has the merit of being less fugacious than many of its congeners. I have grown this species for five or six years, but never succeeded in flowering it before.—H. HALPERN CREWS, *Dryton-Beauchamp Rectory, Tring*.

Carter's White Advancer French Bean.—I have forced this in quantity this year and have found it to be very productive, the pods being long and very tender. This variety and Osborn's Early Forcing are two of the best that can be grown for winter forcing. Where room can be spared, the Canadian Wonder is by far the largest-podded and most productive of all the race, and invaluable for showing. It is likewise an excellent variety for growing in the open air, being nearly as productive as Scarlet Runners.—WILLIAM TILBERRY, *Welbeck*.

Golden Elder.—This is by far the most showy and effective yellow shrub yet introduced; its foliage is golden-yellow, a colour which it retains from spring until autumn. It is a very valuable shrub for planting amongst Hollies, Yews, or dark-folaged Firs for effective contrast in pleasure-grounds, wood-walks, and drives. It may be propagated as easily as a Willow by means of cuttings, and it will thrive in any soil or situation; indeed it is as vigorous and hardy as the common variety.—A. FORRESTER.

An Edible *Yucca* (*Y. baccata*).—Messrs. Hoopes & Thomas, of Philadelphia, cultivate this plant. It is a rare native species found in Utah, Colorado, recently introduced into cultivation. The leaves are very thick, long, narrow, and concave; the flowers are showy, bell-shaped, white, and exceedingly fragrant, and are said to be succeeded by agreeable, sweet, edible fruit.
